SURGICAL INTERVENTION IN PROLAPUS UTERI, RECTOCELE, AND CYSTOCELE.—Dr. Bourdon, after giving several methods of operating in these accidents, offers the following conclusions. In cases where the prolapse, rectocele, or cystocele has appeared suddenly, the displaced organ should be replaced as quickly as possible. The practicable operations are not so dangerous as to cause hesitation in performing them where pessaries are found useless or inapplicable. In choice of an operation the age of the patient should be taken into account. In women who have passed the period of the menopause, the vagina and vulva may be completely obliterated. Perineoraphy is always indicated when laceration of the perineum exists, and often when the vulvar opening is too large. It can be combined with other operations. The simple restoration of the perineum is often sufficient to enable the patient to carry a pessary previously inapplicable.

The process by vaginal flap is preferable where there is laceration without rupture, but where rupture of the perineum exists the process of MM. Demarquay and Lefort, by rectal and vaginal flaps, may be employed. These flap-processes have the advantage over others of less frequently resulting in fistulae, and of making a narrow recto-vaginal septum which restrains the bulging of the rectum in rectocele.

Perineoraphy by the vaginal flap may be useful in cases of simple rectocele with laceration of the perineum; it should always be accompanied by episioraphy. This mixed operation is always practicable in aged women, and serves in cases where operations intended for narrowing the vagina are impossible to maintain in its normal position a voluminous or long-prolapsed uterus. The vulva in these cases should be almost entirely obliterated, as it is frequently less painful to an aged woman to have the vulva closed than to wear a pessary. Complete obliteration is useless, and has even at times caused serious inconvenience.

The best process of perineo-episioraphy is that of Kuchler, by which a solid barrier is formed in front of the vagina, capable of resisting the pressure of the viscera. Elytroraphy serves often with young women where it is not desired to narrow the vagina too greatly, and where the uterus is not too large or the prolapse too old. The first process of Sims, with Verneuil's modification, is excellent when used in the case of simple but voluminous cystoceles. Simple rectoceles and cystoceles may be relieved by Huguier's operation, or by the *pincés électro-caustiques* of Desgranges. The last process of Sims, modified, if desired, by the omission of the longitudinal "freshenings," is advisable in the case of young women, since only the bottom of the vagina is narrowed. Elytroraphy should be practised anteriorly or posteriorly, according to the predominance of cystocele or rectocele.—*Bull. Gén. de Thérap.*, Nos. 6 and 7, 1874. A. V. H.

VARIATIONS IN THE PROPORTION OF WHITE BLOOD-CORPUSCLES IN DISEASE.—M. Brouardel has ascertained by actual count that the proportion of white corpuscles in the blood varies considerably in certain diseases, according to the affection and the period of its course. In variola the white corpuscles appear to be augmented during the almost apyretic period which separates the fever of eruption from that of suppuration, they seem to diminish at the moment when the latter makes its appearance, and if, during the fever of suppuration or desiccation, the number of white corpuscles is seen to become augmented anew, it may be predicted that the patient is about to suffer subsequent suppurations, furuncles, abscesses, etc.

Other researches of M. B.'s, undertaken in patients who had recently suffered from wounds or operations, seemed to show that during the days following an operation the number of white corpuscles in the blood becomes augmented until they stand in proportion to the red globules as one to eight; that after suppuration is established the number of white corpuscles diminishes considerably; and finally, that if during suppuration the number of these latter augment anew, it cannot be predicted, as in variola, that new abscesses are impending.—*Gazette Méd. de Paris*. A. V. H.

A CASE OF CAMPHOR-POISONING.—Dr. Edward Polak (*Wiener Med. Presse*) has been induced, by noticing the report of a case of camphor-poisoning in a late journal, to publish the details of a case of this rare form of poisoning which came under his own observation. On the night of the 9th of May, 1873, he was called to a patient, and upon his arrival found a woman lying upon her back in bed and tossing her hands and feet uneasily about. Her face was strikingly pale, the eyes bright and shining, there was a moderate tension of the entire muscular system, and in the lower extremities slight cramps. The skin was cool but dry, the pulse strong and full, and beating 88 in the minute. The temperature was 38.4°C. A strong smell of camphor was perceptible in the expired air, and also upon that which was expelled by eructation. The patient was in full possession of her faculties, had vomited some warm milk which had been given her, and spoke in a low tone of voice. She complained of violent ringing in her ears, giddiness, oppression of the chest, a sense of fulness in the stomach, and from time to time of her legs falling asleep.

When the cause of her being in this condition was inquired into, it was found that the patient had taken two tablespoonfuls of camphor mixed with brandy and water. A short time after swallowing the dose she became unconscious, and after a time vomited five or six times, and among the matters which were thrown off in this way were found numerous pieces of camphor

of the size of a pea or a grain of Indian corn. She had taken the camphor upon the advice of a female friend, with the object of avoiding any further increase in her family, as she already had four children. Dr. Pollak treated the case with irritating enemata and wine and coffee, and ordered the application of cold compresses to the head, and in a short time the patient fell asleep. She broke into a profuse perspiration, and passed a considerable quantity of clear urine, which had a distinct odor of camphor. The perspiration had no odor except that usually noticed. The nausea and the subjective symptoms noted above speedily ceased, but for nearly three weeks the patient had more or less muscular weakness, giddiness, and gastric disorder, all of which symptoms, however, speedily yielded to treatment. The camphor did not effect the object with which it had been taken, for in due time the patient, then in full health, became for the fifth time a mother. W. A.

ACUTE ABSCESS OF THE LIVER FOLLOWING CONTUSION OF THE PERINEUM.—Dr. E. Vallin relates in *L'Union Méd.*, Nos. 37 and 38, 1873, the case of a healthy man who had abscess following contusion of the perineum. Some time after the healing of this abscess, which pointed near the anus, and seemed purely local, the man was attacked by chills, fever, and night-sweats. At the same time enlargement of the liver was observed, with great tenderness in the right hypochondriac region; the patient emaciated rapidly, and the case seemed likely to terminate fatally.

Suddenly one day, however, the man, who was making an effort to vomit, "felt something crack inside," and soon after threw up about eight ounces of exceedingly fetid pus mingled with bile. From this moment he grew rapidly better, and recovery soon followed.

Dr. V. explains the case thus: A phlegmon in the ischio-rectal adipose tissue, an abscess, probably extra-aponeurotic, phlebitis of some hemorrhoidal veins by which putrid material was conveyed to the inferior mesenteric and thence to the portal veins, thus giving rise to an abscess of the liver, which, opening into the stomach, spontaneously terminated rapidly in recovery. A. V. H.

INFLUENCE OF MUSCULAR EXERTION ON THE METAMORPHOSIS OF ALBUMEN.—Some experiments performed on himself by Dr. Schenck, and published in the *Archiv für Exper. Path. u. Pharmacol.*, possess considerable interest as bearing upon the question of the relation of urea to exercise. While consuming food the exact nitrogenous contents of which were known, Dr. S. placed himself under various conditions of rest, exercise, and sleeplessness, examining with the utmost care his daily excretion of urea.

Two series of experiments were performed, one in winter, the other in summer, and the result, according to Dr. S., shows no direct relation between the performance of work and the excretion of urea. Sometimes while work was being performed to a very considerable amount the urea instead of increasing would decrease, and *vice versa*. Further researches would seem advisable to throw light on this side of the question. A. V. H.

WHOOPIING-COUGH.—Bromide of ammonium in doses of gr. iss to gr. v three, four, or more times a day, with the use of a four per cent. solution of bromide of potassium by means of the atomizer or vapor-inhalations.

CARBOLIC ACID is recommended by Ebstein and Müller for internal use in diabetes. Five to seven grains may be administered daily, in divided doses.

THERAPEUTIC NOTES.

TOPICAL APPLICATIONS IN OTORRHOEA.—M. Ménière in a clinical lecture on otorrhœa gives the following formulæ as convenient and useful in many cases. Although they cannot always be expected to exercise a curative influence, yet joined to appropriate internal remedies they are in a high degree serviceable.

In "earache" one or two leeches are to be applied behind the ear, which may afterwards be covered with a poultice sprinkled with laudanum. At the same time two or three drops of the following solution may be dropped into the external meatus:

R Aconitiæ, gr. i;
Aqua, f3v.—M.

This solution gives better results than laudanum, chloroform, etc., so frequently used. Should the pain be intense, general anodynes may be employed. In chronic otorrhœa the external meatus should be kept thoroughly clean by frequent injections of tepid water, and may in addition be painted once a day with the following solution:

R Acid. carbolic., gr. i;
Glycerin., ʒi.—M.

This solution acts very satisfactorily in modifying the character of the secretion; it is sometimes necessary to increase the proportion of carbolic acid. A ten per cent. solution of nitrate of silver painted upon the internal meatus will often serve a similar purpose. M. Ménière frequently employs the following solution in cases of chronic discharge from the ear. It has the advantage that the patient can apply it himself:

R Zinci sulph., gr. iv;
Glycerin., f3ii;
Aqua, f3vi.—M.

Three to six drops are allowed to fall into the ear, which has previously been thoroughly cleansed with tepid water. The head is to be retained in the inclined position from eight to twelve minutes.

The following solution may be used when great vascularity of the bottom of the ear exists, even where there is perforation of the tympanum:

R Plumbi acetat., gr. ss ad i;
Aqua, f3ss.—M.

A NEW APPLICATION FOR OLD ULCERS is always in order, and no apology is necessary for giving the following, which was very highly lauded by a writer in the *Lancet* a year or two ago, and has been made the subject of a communication to one of the French journals, recently. It consists of flour, four ounces; tragacanth, one-half ounce, powdered; acacia, one ounce, powdered; chalk, one drachm; one egg; water, one pint. Put these materials in a stew-pan, and bring them nearly to boiling, then allow the mixture to cool, and add water to form the whole into a thin paste, which may be applied twice daily, without washing off. The ulcer to be covered with a soft rag. The mixture should not be allowed to become sour.

THE BEST METHOD OF USING CHLORATE OF POTASSIUM TOPICALLY.—Prof. Gosselin, having experienced the frequently unsatisfactory performance of this remedy when used locally in cases of mercurial stomatitis, etc., has devised the following method, which he recommends strongly. A concentrated solution of the salt, mixed, if necessary, with a little laudanum to quiet any pain caused by the stomatitis, is placed upon pieces of lint and introduced into the gingival gutters on each side of the mouth. These pieces of lint are to be renewed at short intervals during the day, and may be alternated with the salt in the usual form of a gargle.

SULPHATE OF CADMIUM IN BLENNORRHOAGIA.—M. Gazeau recommends injections of this salt instead of those of sulphate of zinc, on account of its more highly stimulating and astringent qualities. In the acute stage, the injection may be made of the strength of one-half grain to the ounce of water, to be used every two hours. Copaiba may be administered for the first few days, and cases are frequently cured in five or six days. In chronic blennorrhagia the following combination should be used:

R Cadmii sulph., gr. xvi;
Bismuth. subnit., ʒvss;
Aq. dest., ʒiiiss.—M.

Sig.—Inject after each urination.

TREATMENT OF DIPHTHERITIS.—Carbonate of potassium, according to Dr. Kuhn, modifies the action of the mucous membrane of the throat and air-passages generally in such a way as to arrest the formation of false membrane in this disease, or if given early, and in sufficient quantity to cause alkalinity of the fluids of the mouth, may even prevent its appearance. In infants the dose is sixteen grains to one drachm, daily; in adults, one and a half drachms in the twenty-four hours may be administered. In some cases Dr. Kuhn has used lime-water as an adjuvant.

CURE OF FISTULÆ BY CHLORIDE OF ZINC.—M. Simbat, at the Val-de-Grâce Hospital, uses pledgets of lint smeared with the well-known Canquoin's paste, for this purpose, particularly in cases of fistulæ in ano. Its advantage consists in its stimulant action on the walls of the fistula, the ease with which it may be applied, the absence from the danger always accompanying operations with the knife or other instruments, and, finally, the improbability of a relapse after its use.

QUININE IN UTERINE HEMORRHAGE.—Dr. Deneffe uses quinine in cases of post-partum hemorrhage, and also in those hemorrhages so frequent at the period of the menopause.

The dose recommended by Dr. D. is two grains per hour in the form of pills, continued until at least twenty grains have been taken.

CHLORAL IN PREMATURE LABOR.—M. Martineau makes use of enemata containing sixteen grains chloral hydrate in four ounces of water, in cases where premature labor has set in. If the first injection does not quiet the pains, it may be repeated at intervals of several hours. Chloroform is said to be formed in the bowel by the action of the fæces, which are usually alkaline.

FOR CONSTIPATION.—

R Aloës Socotrinæ, gr. xv;
Ext. anthemidis, gr. xv;
Ext. rhei, ʒss;
Zingiberis pulv., gr. viii.—M.

Divide into twenty pills; one or more at night as required.

LOTION FOR FETID PERSPIRATION OF THE FEET.—

R Potassii permanganat., gr. xxx;
Aqua, f3iv.—M.

The lotion to be applied morning and evening, and the feet to be afterwards powdered with lycopodium or starch.

POMADE FOR VENEREAL ALOPECIA.—

R Hydrarg. protiodid., gr. xv;
Axungia, ʒv;
Tinct. cantharidis, ʒiss to ʒiv.—M.

Apply morning and evening, using at the same time appropriate internal treatment.

PHILADELPHIA MEDICAL TIMES.

A WEEKLY JOURNAL OF

MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY

J. B. LIPPINCOTT & CO.,

715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, JUNE 27, 1874.

EDITORIAL.

THE AMERICAN MEDICAL ASSOCIATION.

THE report of the doings of the Association at the meeting in Detroit, which we laid before our readers in a late issue, has given each an opportunity to form his own judgment as to the actions and achievements of the redoubtable organization. Probably most will agree with us that the national body was excelled in the interest of its transactions, as it was in the numbers of participants, by the Massachusetts State Society. Concerning fractures Dr. Sayre certainly offered some remarkable statistics; but the only conclusion which it seems to us can be drawn from the prolonged discussion is that Dr. Sayre's measurements were made too early in the cases to be in any sense decisive. Leaving out of sight this matter, the Detroit gathering does not appear to have yielded any scientific fruits whatever. But then there was no quarrelling. Truly, it is a blessed thing to see brothers dwelling together in unity; but we hope our readers do not have to travel a thousand miles to enjoy four days of peace!

For the sake of our foreign contemporaries, we want to deny emphatically that the convocation was in any true sense representative of the American profession. We do not in any way wish to disparage our Western brethren, but it is a simple fact that by far the largest portion of the leading minds of the profession are to be found in our Eastern

cities. The most influential periodicals, with a very few exceptions, are there issued; the American medical works almost all have such nativity; the chief medical schools of the country are there situated, and the facilities for higher medical self-education, for study and investigation, do there most abound. Yet at the late meeting these cities were scarcely represented at all. Boston, we are informed, sent one delegate, New York thirteen, and Philadelphia nine. Moreover, with very few exceptions, these representatives were not men of prominence at home,—excellent physicians, no doubt, but not writers, teachers, or practitioners of national reputation.

We fear this meeting is but an index of what is to become more and more marked,—a loss of national character to the Association, a loss which we take to be an almost necessary result of the appointment, year after year, of sessions in the far West.

Wisely or unwisely, it was agreed to restrict representation to the county medical societies, and thereby cut off such bodies as our College of Physicians, some of them the very cradles, or rather parents, of the Association. We do not doubt that the College can endure it, but whether the Association can, is another question. To us it is sheer folly to think that men are to be driven into the county medical societies for the purpose of going to the American Medical Association. The trouble has been that when every facility of entrance has been offered, our best men, with few exceptions, all stayed at home; and now it is proposed to get them in by barring the doors. This is allopathy with a vengeance, and calls to mind the familiar allegory of the three wise men of Gotham.

IF anything further were necessary to show the utter worthlessness of the chemical evidence upon which Mr. Schoeppe and Mrs. Wharton were so near conviction, it may be found in the report of Prof. Aiken upon the gas of Baltimore City,—a report which has been severely handled by Prof. P. B. Wilson in the *American Engineer* of the same city. In it we are told, *inter alia*, that sulphurous acid is very probably present in the gas, and also that “ammonia is always present, and apparently in a very unnecessary quantity.” In all seriousness, remembering that one poor and probably innocent colored woman has been hung upon the testimony of the chemist who publishes officially such nonsense, is it any wonder that some feel indignant at this prostitution of the sacred calling of expert?

CORRESPONDENCE.

DOINGS OF THE NEW YORK SOCIETIES.

Action of Quinine on the Ear—Hydrophobia—Morbid Impulses—Tapping in Pyonephrosis—Treatment of Sciatica.

NEW YORK, June 12, 1874.

A FEW weeks since, a paper was read before one of the prominent societies of this city, by Dr. Roosa, upon the Etiology and Treatment of the Diseases of the Internal Ear, in which he referred to the action of quinine as a remedy. He asserted that when given where congestion of the internal auditory apparatus already existed, quinine would aggravate the disease, and, therefore, produce cerebral congestion.

Dr. Jacobi did not agree with Dr. Roosa, but contended that quinine produced cerebral anæmia, and therefore it was a proper remedy to administer in that condition of the auditory apparatus spoken of.

Dr. Hammond agreed with the first-named gentleman; but, in order to test his convictions, he experimented upon himself, assisted by Dr. Roosa. Before the experiment was begun, his ears and eyes were examined by the auriscope and ophthalmoscope, and found to be in a normal, uncongested condition. He then took quinine, with the results anticipated. The blood-vessels of the tympanum and retina exhibited marked congestion. A dog was also experimented upon. After trephining the skull, quinine was given. A tube was then inserted into the opening. At the lower end of this tube a very thin membrane had been placed, and in the tube a colored fluid. The apparatus being inserted into the skull so that the thin membrane would touch the dura mater, a short time after the administration of quinine the fluid began to rise, and continued to rise for several hours; when, as the influence of quinine began to disappear from the system, the fluid in the tube began to descend, until it finally settled down to its original position, showing most conclusively that the action of quinine upon the brain is to induce a greater amount of blood to flow into it, thereby producing congestion, and consequently leading one to infer that the theory of Dr. Roosa is correct.

While upon the subject of dogs, it may be well to speak of hydrophobia. Dr. Charles P. Russell lately read an elaborate paper upon this subject. After sketching at length the history of the disease, he touched upon the question whether there was any truth in the commonly-accepted theory that hydrophobia is more prevalent during dog-days, or the summer months, than at any other season of the year. While it prevails to a greater or less extent at all seasons of the year, yet, according to a table made in the last century, it appears that out of 2407 dogs affected with hydrophobia there were in the spring 671, in the summer 580, in the fall 583, in the winter there were 573. According to this statement, the summer presents comparatively very few cases. He argues, therefore, that the muzzling of dogs during hot weather is not only unnecessary and barbarous, but tends to worry a dog into the commission of acts, while trying to overcome the discomforts of a

muzzle, which he would not otherwise be guilty of. He thinks that the best method of preventing depredations by the canine population is to place upon them a heavy tax. Worthless curs would soon disappear, and valuable dogs would be taken care of.

Before the New York Medico-Legal Society Dr. Hammond read a paper on Morbid Impulse considered in its Medico-Legal Aspect. He arrives at the following conclusions:

1. A person aware of the existence of an impulse to commit crime, and which he fears he may not be able to resist, is bound to do everything in his power to render the accomplishment of his propensity impossible. It is his duty to place himself immediately under restraint. If he does not, he is morally and legally in no better position than a ruffian who feels an impulse to acquire other people's property and accordingly murders the man most convenient for his purpose.

2. The individual who is clearly shown to have yielded to a previously unfelt impulse to commit crime, and who, accordingly, perpetrates an otherwise motiveless offence, or one which in his normal condition would evidently not have been committed, is too dangerous to society to be allowed to go at large. He ought to be placed under permanent restraint.

3. Those morbidly constituted individuals who commit crimes because it is pleasant for them to do so, should be treated like other offenders against the laws.

4. The fact that a murder has been committed in order that the perpetrator might secure his own execution, is not a palliating circumstance. Those who contend that it is, seem to be actuated by the erroneous idea that suicide is necessarily the act of an insane person.

5. A morbid impulse to crime experienced by an insane person demands continued sequestration.

6. But the plea "I could not help it," is one which every member of the criminal class can urge with as much force as the subject of morbid impulse, and, when it stands alone in an otherwise sane individual, should be absolutely disregarded by juries and judges.

At the N. Y. Pathological Society Dr. Loomis exhibited a fluid which he took as a text upon which to remark concerning a new operation in surgery introduced to the profession by Dr. F. D. Lente, of Cold Spring, N.Y. It was for a disease designated pyonephrosis, or an accumulation of pus in the kidney. The operation consists in cutting down upon the kidney through the quadratus lumborum muscle, and inserting a canula or tube for the purpose of effecting a drain. Dr. Lente's patient recovered. The patient of Dr. Loomis, a Bellevue Hospital case, did not recover. The case went on well for a few hours, but a sudden change supervened, and he died. The operation is spoken of very highly in this city, and deserves to be tried again under more favorable circumstances.

In a paper read by Dr. T. M. B. Cross, upon the subject of sciatica, he described a method of treatment which, although not altogether new, yet is sufficiently interesting and important to forward you. It is appli-

cable especially in those cases not dependent upon causes which require a specific mode of treatment, such as malaria, pressure, and the like. Let a line be drawn from the trochanter major to the tuberosity of the ischium, bisect the line, and let fall a perpendicular; at about four inches down the perpendicular and one inch externally to it will be a point where the great sciatic nerve may be reached most conveniently. It lies about from one inch to one and a half inches below the external surface of the limb. Now take a very delicate subcutaneous syringe (having previously placed in it about four minims of Magendie's solution of morphia), and carefully puncture the limb a sufficient depth to enter the nerve or the sheath of the nerve, and inject the solution. The sensation will be a thrill along the course of the nerve, and a tingling or formication in the foot, if successful; at any rate, the pain will soon cease; and sometimes one application will suffice to cure a very obstinate case. After awhile the thrilling sensation after injection ceases, which indicates that the dose may be diminished, and finally omitted. He recommended the continuous current also, either in conjunction with the injection or separately.

PROCEEDINGS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

THURSDAY EVENING, APRIL 23, 1874.

THE PRESIDENT, DR. WM. PEPPER, in the chair.

DR. R. M. TOWNSEND presented a specimen of *undescended testicle, and medullary sarcoma of the testicle, occurring in the same individual*, and read the following history:

Saturday, April 4, 1874, I was consulted by D. R., mate of a transatlantic barque, on account of a supposed hernia. He was wearing a truss at the time that had been ordered for him in Liverpool. He gave the following history. He is 32 years of age, a native of northern Prussia, and has followed the sea since his fourteenth year. When six years old, he fell upon a plough, inflicting a severe bruise upon the perineum. He first noticed his present condition three months ago, as a swelling within the scrotum. At the end of two months it had sensibly increased, and considerable pain had become incorporated with it. For the past month both pain and swelling have been rapidly progressive: the former, especially, so severe that for the last fourteen days of his trip to this port he was incapacitated for work, and had to keep his berth.

Examination of the tumor, after removing the truss, revealed a tense mass with an obscure feeling of fluctuation. It was evidently not a hernia, presenting none of the characteristics of that affection. The introduction of an exploring-needle failed to bring away anything but a few drops of blood. I was unable in my examination to detect the presence of either testicle other than as a component of the mass. There was no enlargement of the cutaneous veins of the scrotum, or of the neighboring lymphatics. The man's general health was good, and he presented no evidences of a cachexia. He denied any venereal taint, and, with the exception of yellow fever in the West Indies, all forms of previous sickness. His mother is living and healthy, as

likewise are four sisters. His father died of rheumatism two years ago.

Some degeneration of the testicle being manifest, an operation, in the shape of an exploratory incision, and, if necessary, removal of the affected organ, was proposed as the surest means of relief. The patient assenting to this proposition, he was accordingly placed under the influence of ether, April 15, and, with the assistance of Drs. Maury and Graham, I removed the organ. Previous to the preliminary incision the feeling of fluctuation seemed to be so well marked that I was induced to introduce an aspirator. Nothing came away, however, but a few drops of frothy blood. As soon as an incision was made into the testicle a brain-like matter immediately protruded itself. The finger alone was used to clear away the mass, and after it had all been removed the vaginal tunic shone out clear, white, and unaffected. The latter, after ligation of the cord, was removed. But a few drops of blood were lost during the operation.

The removal of the diseased testicle revealed that its fellow had not descended. As the man has had both sexual desire and intercourse, however, since within a time that the descended testicle must have been utterly destroyed, it bore out the inference that one testicle had failed to descend. Examination failed to reveal its whereabouts.

A careful microscopic examination of the removed mass was made by Dr. Bertolet, who reports as follows:

"The softer portions of the growth are made up of a large round-celled parenchyma. The nuclei are also of a relatively large size, and surrounded with granular protoplasm. The intercellular network is well developed, has a soft consistence, and at many points is hyaline, at others again, finely fibrillated.

"The greater part of the tumor presents these microscopic appearances, as briefly mentioned, and can therefore be designated as a *medullary sarcoma*. But there are noticeable at several points hard lumps, not much larger than a pea, which are very firm, white in color, and transparent on thin section. These lumps, upon section, were found to be true hyaline cartilage, requiring, therefore, no further detailed description.

"It was only in a few portions of this pulpy mass that any traces of the tubuli seminiferi were discoverable, but these were so characteristic, and the tubuli distended with irregularly-shaped epithelial cells presenting many protuberances, so as to leave little doubt that active proliferation of the epithelial elements had occurred, and that this mixed growth is to be regarded as being in part carcinomatous, as well as sarcomatous."

May 2.—The ligature came off the cord.

May 9.—The patient has convalesced, and goes to sea again in two days. Since the operation he has suffered severely from colicky pains and constipation. A teaspoonful of the fluid extract of taraxacum at night, followed by a saline in the morning, finally gave relief.

DR. R. M. BERTOLET said the testicle was one of the favorite seats not only of all the varieties of sarcoma itself, but also of all the histioid formations found in sarcoma. It is in the testicle that we have the best opportunity of studying heterologous formations. We have here occurring not only the cartilaginous, but as well the adipose, striped, and unstriped muscular tissues, and the different forms of fibrous and myomatous tumors. Indeed, there are sometimes here recognized all these varieties alongside of each other. Enchondromata and myomata may occur as primary growths, go on for a time without giving rise to serious trouble, but finally become painful. A growth may be originally sarcomatous, and after a time in it may appear the elements of cartilaginous or muscular tissue. We have in this instance a sarcoma in the interstices of which are found cartilaginous elements.

But what is perhaps more important to the surgeon is the course of the disease. Sarcoma starting from the testicle, and not from the epididymis, is generally retained for a time by the tunica albuginea, but if this membrane is once broken the growth spreads very rapidly, entering the cavity of the abdomen and involving the retro-peritoneal glands. If this growth, therefore, has not extended along the spermatic cord, although the medullary sarcomata, as well as the medullary carcinomata, are in the highest degree malignant, there may be no further extension of the disease.

Dr. H. B. REED presented, for Dr. H. B. HARE, a specimen of *aneurism of the abdominal aorta*, from T. W., æt. 44, married, who was admitted to the Episcopal Hospital, April 8, 1874, suffering from severe pain in the epigastric region.

It was difficult to get a satisfactory history from him, but so far as could be learned he had enjoyed average health until the summer of 1873, during which he suffered from time to time from some abdominal uneasiness. He had been in the habit of drinking moderately, though not to excess, and attributed his slight symptoms to dyspepsia, arising, possibly, from this cause.

Towards the end of the summer, in attempting to move a piece of furniture, he thought he felt "something give way inside of him," and suffered slight pain, which soon wore off, leaving no great impression on his mind.

In the early autumn he found his strength failing, though, except the slight abdominal distress, no particular symptom attracted his attention, and in the month of October (1873) he was admitted to the hospital, where a diagnosis was made of cirrhosis of the liver,—a diagnosis fully borne out by the post-mortem appearances.

He stayed in the hospital at that time but a few days, leaving it of his own accord, and returned to his business of tailor. Gradually he became unable to attend to this, and by Christmas-time would have occasional paroxysms of sharp pain at the epigastrium. These increased in frequency and violence, and he noticed by the end of January that they were apparently induced or aggravated by taking food. About this time, also, but not, so far as could be learned, before, slight pain in the *lumbar* region was felt.

Gradually the pain in the epigastrium increased, until at length by March the paroxysms became at times almost unendurable, and he acquired the habit of taking large doses of opium to allay them, which it would do. His appetite, which had been fair up to this time, decreased, and he became emaciated. He had no pain of any kind except at the epigastrium, where it was paroxysmal, and in the lumbar region, where it was almost constant and dull.

On admission he was quite emaciated, sallow, and low-spirited. Examination of the epigastric region revealed a spot about an inch square, at which a thrill was perceived at the slightest touch. Under this spot, it afterwards appeared, the left lobe of the liver was forced up against the abdominal parietes by the aneurismal sac. Elsewhere firmer pressure was needed to detect the thrill, but on auscultation a very loud blowing sound was heard, most marked at the epigastrium, but audible over the whole anterior surface of the abdomen. There was some prominence of the abdomen, and abnormal firmness at, and for a few inches below, the epigastrium. Posteriorly no thrill of any kind could be detected, but careful auscultation revealed a very faint blowing sound to the right of the spinal column and on a level with the twelfth dorsal vertebra. This sound could not be detected anywhere else posteriorly.

No change of any kind was detected until the after-

noon of his death, three days after admission, when he was attacked by violent pain in the region of the heart; and while the resident physician was endeavoring to relieve this, the man began to sink. He died shortly afterwards. Before his death, palpation showed that the tension of the abdominal wall over the aneurism had been removed; this occurred about three minutes before his death.

Autopsy by Dr. H. B. Reed, twelve hours after death.

The *heart* was fatty, and contained some fibrous clots. The lungs were congested, and there were pleuritic adhesions.

A broad, thin, fibrous clot hid from view all the abdominal viscera, with the exception of the liver; the left lobe of this organ was folded upon itself, and held in that position by adhesions.

After the removal of this clot the intestines were exposed to view. They occupied "in toto" the left iliac and left lumbar regions, they being forced into this position by a large clot of blood which occupied the corresponding regions of the right side. This clot, caused by the rupture of the aneurism, contained the right kidney. The *pelvic cavity* was filled with serum. The *spleen*, *intestines*, and *left kidney* were, to the appearances, in a healthy state, but anæmic. The *spleen* was, however, much smaller than natural.

The situation of the aneurism was over the eleventh and twelfth dorsal and first lumbar vertebræ. In character it was sacculated, springing from the posterior wall of the abdominal aorta. The eleventh and twelfth dorsal and the first lumbar vertebræ were eroded by the pressure of the aneurism.

Dr. O. H. ALLIS asked as to the *degree* of pulsation in the femoral arteries.

He stated that he had lately, through the courtesy of a medical friend, seen a case presenting two very prominent symptoms of aortic aneurism, viz., pulsation and murmur. In this case the force and volume of the femoral pulse were most striking features, and suggested at once the improbability of aneurism.

He desired an expression of the clinical experience of the members present upon this point, as in his own mind it was clearly impossible for an aneurism to exist and not materially affect the *force*, *volume*, and *character* of the blood-current beyond.

The PRESIDENT said it was a matter of comparatively frequent observation that aneurism of the abdominal aorta interferes in a singularly slight degree with the pulse in the femorals, much less than aneurism of the ascending aorta and arch with the pulse in the great vessels coming off of it. This he thought was partly because of the fact that in the former instance the lumen of the vessel was much less interfered with; the tumor frequently springing from one side. It is also true that the arterial system beyond the tumor is at times enlarged, so that there is increased pulsation of the vessels from this cause. It is further the case that the heart sometimes becomes hypertrophied, so that there is increased pulse from this cause also. In this case also he thought it might be interesting to discuss the cause of the aneurism, as the arteries appeared uniformly healthy, and there was no syphilis.

He asked Dr. Reed whether there had been any traumatic element in the history of the case.

Dr. H. B. REED, in reply, alluded to that part of the history which stated that some time previously, while moving furniture, he had felt something give way, and that for a short time afterwards he had had pain and uneasiness in the abdomen, but that these had passed away, and he had not been troubled for some time.

Dr. C. B. NANCREDE asked whether the localized pulsation could not be explained through the influence of the sympathetic plexus supplying the femoral artery. Would not the abdominal aneurism press on the solar

plexus and abdominal sympathetic, and thus influence the pulsation? Dr. N. had known a case of abdominal aneurism lower down, in which there had been profuse diabetes insipidus, also, perhaps, explainable through some influence on the sympathetics.

The PRESIDENT said he was not aware that this explanation had ever been advanced to explain the increased pulsation of the femorals under such circumstances. It is generally recognized that a certain degree of disturbance of the sympathetic will produce local pulsation of the vessels supplied by the part of the nerve affected; as in cases of exophthalmic goitre. And, further, it is certain that the abdominal ganglia of the sympathetic are often implicated in cases of abdominal aneurism. This is shown not only by post-mortem dissections, but during life, by the disturbances of secretion of the mucous membrane and of the skin of the lower part of the body. In some cases, published by himself a few years ago, profuse secretion had been observed in connection with abdominal aneurism; and in one very singular instance, when the patient turned from one side to the other there was a complete change in the area of the sweating, the half of the body on which he was lying becoming bathed in sweat, while the opposite half would dry off.

Dr. JOHN ASHHURST, Jr., said that he thought the differences observed in various cases in regard to the degree of pulsation noticed in the arteries below the aneurismal tumor were mainly to be accounted for by the condition of the aneurismal sac in each particular case. The diminished pulsation commonly met with he believed to be chiefly due to the mechanical action of the sac-walls in equalizing the blood-current and thus lessening pulsation, just as the air-chamber does in the ordinary "hydraulic ram." This action would probably be less marked in a sacculated than in a fusiform aneurism, and it would also vary with the condition of the sac as regarded the presence of laminated clot, which if existing in large quantity would of course diminish the resiliency of the part.

With reference to the *causation* of the aneurism, Dr. A. thought that it was not uncommon for the development of the disease to be traceable to an injury such as was met with in the case under discussion. A man receiving a sudden blow, or making a violent lifting or straining effort, might suffer rupture of the inner coat of the aorta or other large artery, perhaps at the time experiencing the sensation of something having given way, and a few weeks afterwards an aneurism would be found at the point of injury. This might occur whether the vessel were healthy or diseased, and many aneurisms thus resulted from injury which yet were not classified as "traumatic."

The PRESIDENT asked Dr. Ashhurst whether much importance could be attached to the stand-pipe action in the diminished pulsation of the vessels of the neck and arm attending aneurism of the arch of the aorta. Is there not often to be found an alteration in the mouth of the artery whose pulsation has been most influenced? In all cases where there had been marked diminution in the radial or carotid pulse, he had found after death that, owing to the stretching of the walls, the corresponding orifice was slit-like, and therefore greatly diminished, or that the walls of the artery shared in the atheroma of the larger vessel, and that its orifice was therefore more or less occluded.

Dr. ASHHURST said that no doubt the President's explanation was applicable in certain cases, particularly in those of aneurism of the aortic arch; in other cases the direction in which the growth of the sac occurred was to be taken into account, the pressure caused by the enlarging aneurism sometimes impeding the circulation in the artery on the distal side of the sac, and even, it was said, thus leading to the cure of a second aneurism

when two existed in the course of the same vessel. The chief and most important cause of diminished pulsation, however, he believed to be that to which he had already referred, viz., the mechanical action of the sac-walls.

Dr. H. LENOX HODGE exhibited the *carpus and articular extremities of the radius, ulna, and the second and third metacarpal bones*, which he had removed this day at the Presbyterian Hospital, on account of chronic arthritis of the wrist. The patient is a man about 35 years of age, who has suffered from chronic arthritis for the last two years. The pain has been very great. Abscesses have formed and have been discharged on the back of the hand, on the front of the fore-arm, on the palm of the hand, and on the palmar surfaces of thumb and forefinger. The excision was done after Lister's plan. The lower ends of the ulna and radius, including the radio-ulnar articulation, the whole carpus except the pisiform bone and the hooked process of the unciform, and the carpal extremities of the metacarpal bones of the forefinger and third finger, were removed. The carpal extremities of the metacarpal bones of the thumb and of the fourth and fifth fingers were healthy, and, contrary to Lister's recommendation, were allowed to remain. In excision of the knee-joint no harm results from leaving part of the femur covered with its cartilage if healthy. It was, therefore, thought that in the case of the wrist also, healthy bone covered with sound cartilage could be left without danger, and that these carpal extremities of the metacarpal bones would add to the future usefulness of the hand. Above the section made by the saw there was an abscess in the radius: to this the gouge was freely used.

Such extensive disease of the wrist is comparatively rare. It is the first case which Dr. Hodge has seen in which he thought excision necessary. In this case, as well as in a number of others of similar nature, Dr. Hodge has made use of Esmarch's apparatus for the prevention of hemorrhage, with great satisfaction. There was no bleeding during the operation, and no ligature was requisite after the elastic band was removed. All tendency to hemorrhage was arrested by dry lint.

Dr. ALLIS asked whether new sheaths are formed over these exposed tendons after this operation, and whether they are lubricated by the same fluid as in health.

Dr. Hodge said he had avoided opening the sheaths when he could. The tendons which were divided, and of which the sheaths were, therefore, also divided, were the extensors of the wrist, the two radial, and the ulnar. One portion of the common flexor of the fingers was also partly exposed, but not so as to interfere with its sheath. The tendons were divided at the extremity of their insertion, and therefore the lubrication of the sheath would remain in its totality. The one most difficult to avoid is the ulnar extensor, and he was therefore careful to cut between it and the bone, and thus to preserve all its surrounding structures. He thought that if this operation was carefully performed, the sheath of the tendon would not be injuriously interfered with.

The PRESIDENT read the following notes of a case of typhoid fever with unusual symptoms, and exhibited the specimens.

Typhoid fever—Anomalous course of temperature—Marked symptoms of spinal irritation—Death on ninth day (?)—Characteristic lesions.—John Keller, æt. 38, German. On admission, 4th of April, 1874, complained of dyspeptic symptoms, with constipation. He seems to have improved under treatment, and was only seen in the wards at meal- and bed-times. On the 8th he was noticed by the night-nurse to have a staggering gait; he was stupid, and temperature 101 $\frac{3}{4}$ °. Next morning temp. was 104 $\frac{3}{4}$ °; pulse 102. Hardly any history could

be obtained from him; he had been living about Front and Race Streets.

Much stupidity, and at times a condition of comatosis. Marked tremor, and great rigidity of all the muscles. No eruption, no sordes; constipation; slight meteorism; no tenderness; apparently nowhere any pain; urine high-colored, not albuminous, with slight diminution of urea; had to be drawn with catheter. No cough or sputa. Physical examination: resonance rather exaggerated anteriorly; dulness over the two bases posteriorly; marked absence of respiratory murmur throughout the lung. A double pericardial friction-sound heard at the base of heart. 9th, evening temp. 104° ; pulse 120. 10th, morning temp. $103\frac{1}{2}^{\circ}$; pulse 125; resp. 30; evening temp. 103° ; pulse 144; resp. 30. At 11.45 P.M. he was found unconscious, rigid, motionless; temp. $106\frac{3}{4}^{\circ}$; pulse 145; resp. 45. He was packed in cold sheets wet with cold water for two hours, when temp. fell to $101\frac{1}{4}^{\circ}$. During the day and night of the 11th the temperature showed a constant tendency to rise, so that only by repeated packing could it be kept between 100° and 103° . At 10 P.M. it reached 105° , but was soon brought down to $100\frac{3}{4}^{\circ}$; finally, at 6 A.M. of the 12th, he died, with a temperature of 105° . His other treatment has consisted of quiniæ sulph., grs. xxiv daily, concentrated nourishment, eight ounces of whisky daily, and the use of febrifuge draughts.

Post-mortem, ten hours after death.

Thorax.—The lungs were congested, especially in their postero-inferior portions, where they presented a condition approaching splenification. The pericardial sac is not distended. On opening pericardial sac, about two ounces of clear serum are found. There is a patch of lymph on the anterior surface of aorta, one and one-fourth inches above the origin. This lymph does not seem recent, as it is tough, and there appear to be new-formed vessels. There are several milk-spots over surface of the heart.

Heart.—The cavity of the left ventricle almost obliterated by firm contraction of walls, without contents. The right ventricle contains a little dark fluid blood. No lesion of the valves. The lining membrane not stained.

Abdomen.—There is marked retention of warmth. The liver is of moderate size; its tissue pale, somewhat congested. The spleen double the natural size; tissue much softened; no abnormal deposit. The mesenteric glands greatly enlarged, pinkish, and dry. The *intestines* greatly distended with gas, and containing fluid fecal matter. The lower three feet of the ileum were opened; there was marked injection of the mucous membrane. The solitary follicles were greatly enlarged, and Peyer's patches, especially towards the valve, were also enlarged, with prominent raised borders and enlargement of the orifices of the follicles. The patches were of a pale grayish color (medullary infiltration).

Head.—Vessels of the dura mater were slightly injected. The arachnoid over the convexity near the sinuses and along some of the larger veins was milky and thickened; chronic inflammation. No abnormal effusion.

Kidneys.—Cortex pale and probably fatty. About one pint of urine was found in the bladder.

Microscopic examination.—The uriniferous tubules were filled throughout the kidney with fatty cells, decidedly granular, and, rarely, some free oil-drops. There was also some degeneration of the liver. The heart-muscle was fatty; the fibrillæ being granular throughout, though the striation was yet perfectly distinct. There was no degeneration of the voluntary muscles. Portions were examined from the pectoral and rectus muscles.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

A CONVERSATIONAL meeting was held February 25, 1874, at 8 o'clock P.M.

The PRESIDENT, DR. W. L. ATLEE, in the chair.

Dr. W. B. ATKINSON remarked that he had been recently treating a large number of cases of measles, and had also encountered a few cases of scarlet fever. In this connection, he would call the attention of the members to the use of digitalis. He had been employing an infusion of a drachm of the powder to twelve tablespoonfuls of boiling water; dose, a teaspoonful every two or three hours, according to the age of the patient. He hoped the members would try it and report their results. He had never seen any of the so-called cumulative effects of this remedy. He had used it in this way for many years, and always with markedly good results in twenty-four to thirty-six hours. He had previously employed the various modes of treatment suggested from time to time, but had never experienced so much satisfaction from any other remedial means.

While in the midst of an epidemic of scarlet fever many years ago, he had employed the chlorine-mixture, but was much depressed by his want of success. The late Dr. L. P. Gebhard suggested this remedy, and in this form; he at once put it into practice, and was pleased with the rapid amelioration of the symptoms.

Dr. BUCK said he was in the habit of using liquor ammon. acetat. and neutral mixture aa ʒi , with a drachm of tincture of digitalis, a teaspoonful every two or three hours.

Dr. W. L. ATLEE said that he was very much pleased with the remarks of Dr. Atkinson respecting the use of digitalis, as it confirmed his own experience. He had for many years been in the habit of using it in acute diseases, and in all cases of irritability of the heart. He preferred it to veratrum viride, as it is less liable to irritate the stomach, although he sometimes aids its action by administering small doses of the latter medicine at the same time. He had never seen an instance of its cumulative action.

Dr. WELCH had recently met with a few cases of measles. He had quite lately treated three cases in the Municipal Hospital, which had been sent there as cases of smallpox. This mistake occurred in some twenty-five instances during the late epidemic. In regard to the treatment of scarlatina, he said that he had frequently heard the late Dr. Gebhard speak in very sanguine terms of the good results obtained by the use of digitalis. This always seemed to him very much like treating a single symptom of the disease, the rapidity of the heart's action. So far as this particular symptom is concerned he thought digitalis might be of service, but did not think it possessed any antidotal power over the poison of scarlatina.

Dr. ATKINSON in reply said that he had come to regard digitalis as possessing some peculiar antidotal effect upon the poison of scarlatina. For this reason he preferred the powdered leaves in infusion. Of course he employed tonics, when demanded for the after-treatment. He uses this remedy in full doses until the pulse has come down to its normal rate; and then he reduces the dose or lengthens the interval, so as to keep the system under its influence.

Dr. ATLEE asked Dr. Welch whether an eruption resembling measles did not sometimes precede the appearance of smallpox.

Dr. WELCH in answer said the eruption of smallpox is frequently preceded by an eruption closely resembling measles. This usually fades out when the true eruption appears. Its presence is so frequently observed that it has received the name *roseola variolosa*.

Dr. L. TURNBULL then read a paper on Tinnitus Aurium.

Dr. KEYSER asked Dr. Turnbull if he never treats the impaction of the Eustachian tube by syringing it out through a double catheter.

Dr. COLLINS remarked that he had often treated tinnitus, and had often failed. The success of treatment depends upon finding out the cause. In one case of Graves's disease the patient suffered horrible tinnitus. When the goitre subsided and other symptoms abated, the tinnitus ceased. In the case of a young lady suffering from obstruction of the Eustachian tube, by the use of the syringe and Eustachian catheter her hearing was improved. At first she could only hear high-toned musical sounds. He could not explain the signification of the high tones. He had found trouble in the use of double catheters.

Dr. TURNBULL replied to Dr. Keyser that, under the ninth mode of treatment, he had recommended in his paper a trial of the injection of the Eustachian tube by the double catheter, and in his work on the ear he had figured and described the form. In his hands the double catheter was apt to become obstructed, by its fitting too close into the narrow part of the tube, also by the particles of hardened mucus and thick secretion. He preferred a paracentesis of the membrana tympani, and injecting the middle ear with a syringe which has a close-fitting nozzle covered with elastic tubing, into the external meatus, charged with a warm alkaline solution, and afterwards one of stimulating or alternative, such as nitrate of silver, etc., being careful to hold the hand well elevated, so as to avoid the fluid entering the frontal sinus. Another plan is to introduce the Eustachian catheter by the nostril, and, by means of a hand air-bag, blowing the secretion through the perforation.

In reply to Dr. Collins, he said that high tones always give trouble, and yet they were heard even in so simple a disease as "otitis media catarrhalis," or when we have a very concave membrana tympani, owing to the affection of the middle ear causing pressure and hyperæmia of the cochlea. For we consider the cochlea a sort of micrometer of sound. We have also in disease of the middle ear a symptom known as double-hearing, the last tone being repeated or echoed from the same cause. In some recent experiments, Dr. Turnbull has found that but few, and those young persons, who are considered to have good ears, and were also musicians, failed to reach forty thousand vibrations of König's rods (these rods were made with great care for use in diagnosis of diseases of the ear, under the supervision of his friend Dr. C. J. Blake, of Boston, Lecturer on Otology in Harvard University).

GLEANINGS FROM OUR EXCHANGES.

TRANSFUSION WITH LAMB'S BLOOD.—In one of the last sittings of the Medico-Physical Society of Dresden a report was given of sixteen cases of transfusion with lamb blood. Six of them, related by Dr. Oehme, have been conducted at the City Hospital; the others in the private practice of several physicians, Drs. Stetzner, Hirschfeld, and Bischoff. In most of these cases the operation was made on account of tuberculosis pulmonum, in one case frequent hemorrhage of the stomach, in another there were indications of puerperal disease. The phthisical patients selected for transfusion were mostly those in whom the affection of the lungs was only in the first stage of development, while the general symptoms—anæmia, sleeplessness, and deficient appetite—were more prominent. The quantity of blood injected varied from sixty to one hundred and fifty

grammes; the apparatus was constructed accurately as Gesellius uses it for this operation. The first symptoms that appeared after the injection of the lamb blood were very striking, sometimes even alarming. The temperature rose almost immediately to 40° Cels., frequently even to 41° and 42°. Intense dyspnoea, shivering, vomiting, and convulsions were observed in a great majority of the patients. All these symptoms, however, disappeared almost as suddenly as they had come forth, and the patients were able to walk back to their wards or homes. A remarkable symptom which ensued in nearly all cases within the next day or two after the operation was hæmaturia. This phenomenon has been explained by the admirers of transfusion as a consequence of destruction of human blood-corpuscles; but it seems much more natural to suppose that the blood-corpuscles of the lamb were destroyed in the serum of the human blood, just as it has been proved by experiment that the blood-corpuscles of the dog are entirely dissolved in the serum of human blood.

The effect of the operation was almost nothing. Regarding the phthisical patients, neither sleep nor appetite, nor any local symptom, showed the slightest alteration; the weight of their bodies within the first five or six weeks after the injection of blood decreased in the same proportion as before; the same result was observed in all the other cases. One patient (puerperal disease) died two days after the operation, but the autopsy afforded no reason to believe that the fatal end was due to the therapeutic measure.

It seems, therefore, that the wonderful tales related by Gesellius are not quite trustworthy, and that, if transfusion should be necessary as *ultimum refugium*, nothing but human blood ought to be used for the purpose.—*London Lancet*.

OPERATIVE PERFORATION OF THE MEMBRANA TYMPANI.—M. Bonnafont, an eminent aurist of Paris, read on the 26th of May last, before the Academy of Medicine, a paper on this operation. It appears that he has had a delicate trocar and canula constructed; and when the former is withdrawn the latter remains in the tympanum, held by little wings or hooks which mechanically spring up on the withdrawal of the trocar. The canula thus remains in the ear as the style in the lachrymal canal. With very sensitive people, M. Bonnafont first deadens feeling in the membrane by means of the ether spray, and thus prevents such movements of the patient as might render the operation unsafe. The case mentioned in the communication was successful, the hearing having immediately considerably improved.—*London Lancet*.

TREATMENT OF ZONA BY COLLODION AND MORPHIA.—Dr. Bourdon, Hôpital la Charité, after having tried a great many local means for treating the above disease and checking the intense pain, has definitively adopted the following plan: Without opening the vesicles, he paints all the diseased surface with a combination of collodion and morphia,—collodion one ounce, morphia eight grains. The mixture must be put on pretty thickly. The pain ceases from the second day, and at the end of seven or eight days, when the layer of collodion is removed, all the vesicles have disappeared, and there remains only a slight local redness.—*London Lancet*.

SILICATE OF SODA IN GONORRHOEA.—At the Roosevelt Hospital, injections of the silicate of soda have been recently employed in the treatment of gonorrhœa, in both acute and chronic stages:

R Silicate of soda, 20 grains;
Water, 8 ounces.—M.

The injections are given three times a day, with satisfactory results. No other treatment is combined with it.—*The Medical Record*.

SATURDAY, JULY 4, 1874.

ORIGINAL COMMUNICATIONS.

THE OPERATIVE TREATMENT OF PLEURAL EFFUSIONS.

Read before the Philadelphia County Medical Society, March 25, 1874,

BY WILLIAM PEPPER, M.D.,

Professor of Clinical Medicine in the University of Pennsylvania.

IN announcing that I should this evening present a few remarks upon the subject of pleural effusions, I have felt that it would be desirable to pass over the somewhat theoretical questions which may be raised about the diagnosis of these effusions, and to limit my remarks to the more practical and interesting point of their treatment. It is necessary, however, that we should, before entering upon that discussion, determine clearly the extent of our inquiry, and decide upon the precise meaning of several terms which it will be essential frequently to employ. The term "pleural effusion" is evidently the most general one which can be used to denote fluid accumulations in the pleural sac. Nearly all of the other terms which are applied have some special meaning which would properly restrict their application to some single class or variety of these effusions, and undoubtedly it was the original intention of those who introduced these terms that they should convey this specific and limited meaning; but with the course of years, and the varying phases of opinion as to these affections, more and more laxity has crept into our mode of employing them, and in some instances we find them used by authors of eminence with meanings the most diverse.

Among these terms, the most common are the following, which I shall, throughout this discussion, employ with the signification now attached to each:

Pleuritic effusions,—the general term for collections due to inflammation of the pleura.

Hydrothorax,—indicating a serous effusion due to subacute inflammation, to venous stasis, or to changes in the crasis of the blood.

Pyothorax, or empyema,—indicating an effusion which is composed of pus, either pure or mixed with varying degrees of sero-albuminous fluid, and which is, as a rule, connected either with very intense acute inflammation, or more frequently with inflammation occurring in cachectic states of the constitution; and,

Hæmothorax,—indicating an effusion composed in large part of blood. This term is inapplicable to those serous effusions which are merely tinged, sometimes very deeply, with hæmatin, or which actually contain a very minute proportion of blood.

Having thus defined the terms which are used to designate these effusions, it is evident that the treatment adapted to their cure must vary greatly in the different forms. The general methods of treatment applicable are internal and external: among the former may be mentioned dietetic and medicinal means, while the latter include local applications and operative procedures. It will, perhaps,

be most convenient to discuss these separately, with special reference to their practical applications. It will not be thought surprising that I should first call attention to the operative treatment of pleural effusions, in these days when a recent author* speaks in the following words: "Thoracentesis is no longer an operation: it is a prick of a needle, which obviates at once pain and danger." It is quite true, indeed, that the idea of removing large pleural effusions by paracentesis is not a new one. The operation was clearly recognized, and rules for its performance, not very different from those adopted by some modern operators, were laid down, in the writings of Hippocrates. During the seventeenth century, the operation, which had previously been resorted to but rarely, gained great popularity. Scultetus introduced the use of the syringe to withdraw, by aspiration, the portion of the effusion which gravitates below the external opening; and numerous important treatises were written upon the subject. It is, indeed, difficult to conceive how it should have been otherwise, when so many cases were observed where nature effected a cure of long-standing pyothorax by an external opening, and when, in post-mortem examinations, it must have been frequently noticed that the fatal accumulation of serum or pus was confined only by the thin intercostal tissues, which might readily have been punctured. Yet it is to be borne in mind that, until the introduction of physical diagnosis had rendered the detection of pleural effusions as certain and easy as it now is, physicians must have had recourse to the operation with much hesitation and uncertainty.

But few distinct clinical histories remain to us from the earlier days of paracentesis; but doubtless, to judge from the difficulty which even now attends the diagnosis in some cases of pleural effusion, our bold forefathers must have made many a "dry tap."

The more recent history of the operation is somewhat curious. Despite the many instances in which it was known to have been successfully employed, despite the improvements in the mode of operating, and the vast improvement in our power of determining the exact location and extent of the effusion, paracentesis continued to be regarded as a daring operation, to be performed only under conditions of urgent danger. It is true, when Laennec announced his immortal discovery, he did not fail to perceive the bearing which physical diagnosis had upon the operation under discussion, and he asserts that "paracentesis will become much more common and much more useful in proportion to the diffusion of the employment of mediate auscultation." That this prediction was not more speedily verified is to be explained by the fact that there was still wanting a clear analysis of the clinical symptoms which furnish the chief indications for the operation, as well as the sole guide in the prognosis of its results.

The great credit which is due to Trousseau in connection with paracentesis is, then, undoubtedly

* Dieulafoy, *Pneumatic Aspiration*, London, 1873, p. 269.

this, that in 1843 he for the first time gave a clear and impressive account of the precise indications which call for the operation, while at the same time he simplified the operative procedure, and, by his great success in repeated instances, confirmed his precepts by the most extended practice. Becker, Schuh, and Skoda had, a few years previously, published valuable memoirs, which anticipated most of Trousseau's conclusions; but it was reserved for this latter teacher, by his firmness and his eloquent advocacy and brilliantly successful employment of paracentesis, to bring the operation into the high favor which it has since enjoyed. On the continent of Europe, its discussion has been ever since "the order of the day;" and in England it has been frequently advocated and performed.

In America, despite the valuable memoirs of Bowditch, published over twenty years ago, the operation has apparently never been so popular and generally practised as abroad. It may, therefore, not be deemed inappropriate if I give a brief sketch of the operation as it is performed by different operators, and as I have myself frequently employed it. And in speaking of them I shall allude—

1. To the instrument employed.
2. To the point of puncture.
3. To the after-treatment.
4. To the indications for operation.

The first method to which I shall allude may be called that of Trousseau, although the chief peculiarity, the valve in the canula, was the introduction of Reybard (*Gaz. Méd.*, January, 1841). As described in his work on Clinical Medicine (Syd. Soc. Trans., vol. iii. p. 270), the apparatus consists merely of a bistoury, with which an incision is made through the skin at the point to be punctured, and a common trocar, the lips of which are surrounded with gold-beater's skin which is softened by being wetted. When gold-beater's skin cannot be obtained, a piece of the intestine of a fowl, rabbit, or cat, or a bit of bladder, will serve the purpose of forming a valve which will allow the fluid to flow out during expiration, whilst during inspiration it rests in exact apposition to the expansion of the canula and prevents the entrance of air to the chest.

A modification of this method, which I have employed in many cases with entire success, is as follows. A piece of thin india-rubber tubing is attached to the canula, and the trocar is passed through the tubing before entering the canula. The free end of the tubing is placed in a vessel containing a little water. After the puncture has been made, the stylet is withdrawn, the minute hole in the elastic tubing instantly closes, and the fluid escapes into the vessel, the water in which effectually prevents any return of air during the interruption to the flow of the fluid.

As illustrations of the successful performance of this simple operation, the following cases may be cited:

Case I.—Hydrothorax with ascites, following cirrhosis of the liver, and (probably) adherent pericardium; paracentesis; recovery.

W. E., æt. 71, was admitted into the Philadelphia

Hospital on March 25, 1873. He had enjoyed general good health. In 1845 he had rheumatism, with affection of the heart, and since then had more or less palpitation. For the previous six months he had been much troubled with dyspepsia, flatulence, irregular action of the bowels, and occasional nausea; and, within the past two months, ascites had appeared.

On March 20 he had a profuse hæmatemesis, followed by bloody stools, which caused a dangerous state of exhaustion. On admission, he was still extremely prostrate and anæmic, and regained strength but slowly. There was no return of hemorrhage, but the effusion in the abdominal cavity increased, and signs of hydrothorax of the right side appeared. He was placed upon the use of digitalis, squill, and nitrate of potassium, and at first the pleural effusion diminished somewhat, but again increased, and became associated with so much gastric irritability and diarrhœa as to render internal medication impossible. There also occurred now from time to time spells of extreme dyspnœa, with so much disturbance of the heart's action as to be alarming.

The physical signs were as follows. The right side of the thorax was enlarged, with some bulging of the intercostal spaces. There was complete dullness, continuous below with the area of liver-dullness, and extending up to the second rib, above which there was tympanitic resonance. Over the area of dullness the vesicular murmur was absent, and no breathing-sounds were heard, but distant bronchial breathing. Vocal resonance and fremitus were also almost annulled. By careful percussion, distinct fluctuation could be detected in the sixth interspace. Over the apex there was rude respiration. The respiratory movements of the right side were very slight. There were no signs of disease on the left side. The apex-beat of the heart was greatly influenced by the respiration, descending during inspiration to the sixth interspace, a full inch to the left of the nipple-line, and rising during expiration to the fourth interspace, just within the left nipple. There was also distinct retraction of the nipple and soft tissues surrounding it, attending the contractions of the heart. There was neither præcordial thrill nor any friction-sounds or valvular murmurs heard there. The cardiac sounds were feeble, irregular, and often reduplicated.

On May 24, 1873, he had an unusually severe paroxysm of dyspnœa, with lividity, coldness of extremities, feeble, fluttering pulse, gasping respiration, and great prostration; and, on the day following, one hundred and sixteen fluidounces of clear, straw-colored serum were drawn off by a puncture in the sixth interspace, at the line of the anterior border of the axilla. During the early part of the operation the fluid was allowed to flow through an india-rubber tube attached to the canula; the last portion of the effusions was removed by a Bowditch syringe. The patient became so weak as to render it necessary to abandon the operation before all the fluid was withdrawn. Adhesive strips were tightly applied around the right side of the chest. There was an immediate return of percussion-resonance down to the fifth interspace, with vesicular murmur and crackling sounds (expansion râles, mixed with friction-sounds).

The following observations of his pulse and temperature were made before and after the operation:

May	24,	8	o'clock P.M.	Temp.	100 $\frac{3}{4}$ °;	Pulse	97.
	25,	12	"	M.	98 $\frac{1}{2}$ °;	"	66.
"	"	4	"	P.M.	"	99 $\frac{1}{2}$ °;	" 64.
"	"	8	"	P.M.	"	99 $\frac{1}{2}$ °;	" 80.
"	26,	6	"	A.M.	"	98°;	" 73.
"	"	12	"	M.	"	99°;	" 97.
"	"	8	"	P.M.	"	99 $\frac{1}{2}$ °;	" 98.

Since that date he has continued under observation. There has been no return of hydrothorax. The fluid which remained in the pleura, as well as the ascites,

was gradually removed after the operation, under the use of digitalis, iodide and acetate of potassium, and mild laxatives. He is at the present time enjoying fair health for a man of his age. There is still slight dullness at the base of the right chest, and a few friction-sounds are at times heard over the antero-lateral region.

Case II.—Hydrothorax, from chronic subacute pleurisy; fatty degeneration of the heart, and incipient cirrhosis of the kidneys; paracentesis, followed by great relief; return of pleurisy; death from ulceration of colon.

J. L., æt. 72, a huckster by occupation, and much exposed to inclement weather, was first admitted to the Philadelphia Hospital in 1863, with acute rheumatism, and was discharged cured in eight weeks. In 1866 he was admitted to the out-ward department, and remained there, in fair health, though somewhat troubled with weakness and occasional palpitation of the heart. In the winter of 1871–2 he contracted a severe cold from sitting in the draught, and soon afterwards began to complain of increased weakness, feverishness at night, pain in the right side, shortness of breath, frequent, dry cough, and soon afterwards of swelling of the feet and legs. These symptoms increased, and he was readmitted to the hospital on April 26, 1872, with œdema and ascites, and marked dyspnœa, and palpitation and irregular action of the heart. Upon physical examination, there was flatness upon percussion, with great increase in sense of resistance from the third intercostal space downwards upon the right side. The level of dullness varied markedly with alterations in the position of his body. There was decided enlargement of the right side of the chest, with bulging of the lower intercostal space. The respiratory movements were greatly impaired, and vesicular murmur was absent over the area of dullness. There was, however, a transmitted bronchial breathing-sound over the entire lung. The apex-beat of the heart was pushed considerably to the left. He was placed upon the use of tinct. digitalis, gr. xij to xv, with spts. juniperi comp., f3ss thrice daily; and later there was added to this, potassii acetatis, gr. xij, and potassii iodidi, gr. iii, thrice daily. Tincture of iodine was daily painted over the seat of effusion.

His digestion was greatly disturbed, and the above treatment appeared to diminish his power of taking food, while the symptoms of disturbance of respiration and circulation became so urgent that, on June 3, a fine trocar was introduced immediately above the eighth rib, in a line with the anterior border of the axilla, and one hundred fluidounces of clear serum were withdrawn through an india-rubber tube attached to the canula, the free end being carried below the surface of water. No suction-pump was used. The operation was productive of immediate and great relief, and was followed by no rise of temperature, or any unfavorable symptom. The apex-beat of the heart returned to its normal position. The lung expanded; the transmitted bronchial breathing disappeared, and vesicular murmur became audible over the upper and front portions of the chest, while dullness on percussion and feeble bronchial breathing persisted in the most dependent posterior parts of the chest.

There was subsequently so much improvement that he left the hospital again, though with evidences of pleural thickening and with some effusion in the left thorax.

He came under observation again in October, 1873, more than a year afterwards. He was then quite weak, with poor appetite and digestion, and constant tendency to diarrhœa. Heart's action irregular and feeble; circulation sluggish, and œdema of feet appearing during day and disappearing at night. There was no valvular murmur.

The following notes of physical signs were made:

Right chest moved much less in infra-clavicular and mammary regions than the left side. Below the lower

part of the mammary region down to the lower border of the ribs there is a sinking on each inspiration quite marked when compared with the left side. Vocal fremitus increased; from the sixth rib to the lower border of the thorax there is a marked depression anteriorly; posteriorly, the conformation of the two sides is alike. Percussion anteriorly is resonant from the clavicle to the fifth rib, below this it becomes flat; posteriorly it is resonant above and for a short distance below the spine of the scapula, below this it is flat. Auscultation, posteriorly, at the upper part of the chest reveals bronchial breathing which becomes fainter as the lower part of the lung is reached, and low down can be just heard.

Anteriorly, bronchial breathing can be heard as low down as the fifth rib; below this there is with each inspiration a creaking sound; none on expiration. Expiratory murmur can be heard; vocal resonance increased on this side.

Left chest, very resonant anteriorly and posteriorly; respiratory murmur increased over whole of lung; chest just below the clavicle is slightly fuller than on the other side. In inspiration the whole of this side seems to be lifted upward; movements much more free than on the right side. He has no cough, but some dyspnœa, though not enough to prevent him sleeping on his back.

There is well-marked arcus senilis around each eye, and vision is impaired.

Liver-dullness does not extend below the border of the ribs.

Urine passed very freely; has to get up several times during each night to pass it; quantity large. It is normal in color, and contains no albumen; sp. gr. 1008.

His treatment consists of digitalis, tincture of chloride of iron, and quinine, with application of iodine to the chest.

January 6, 1874.—Since the last note he has been gradually sinking, especially during the last three weeks; he has lost flesh rapidly; there has been much diarrhœa, sickness of stomach, and vomiting. The stools have been very watery, varying from a light to a dark color, and sometimes numbering as many as fifteen to twenty in the twenty-four hours. The matters vomited have consisted of food mixed with a yellow liquid, and have at no time contained any blood. His piles, which he has had for a number of years, have been very troublesome lately. His pulse has been very irregular and intermittent, and so very feeble as to be scarcely perceptible at the wrist. Every means was taken to keep up his strength, and to stop the diarrhœa and vomiting; but on January 6, at 8 o'clock A.M., he died.

Autopsy made four hours after death. There was a marked depression on the antero-lateral part of the right chest, at the seventh, eighth, and ninth ribs, over a space about six inches wide and four inches long. The point of puncture was in this area. The scar left by the trocar in the skin was barely visible, and there were no adhesions between the skin and intercostal tissues. Upon the costal pleura there was a minute opening, one-sixth of an inch in diameter, still visible. On opening the thorax, the right lung was found to be compressed, and the pleura tightly adherent. The adhesions were firm all over the pleural surface, but most so at the lower part, where they were very dense, and about half an inch thick. The attachments were so firm that the lungs were with difficulty removed. The adhesions were thickest at the position of the depression of the ribs, above stated; just behind this point there was a small cavity, containing serous liquid, circumscribed by the thickened adherent pleura. The right lung was dark and congested, but still permeable to air. The left lung was normal, but somewhat congested. At the apex of this lung there were some moderately firm pleuritic adhesions; there were none over the rest of the lung.

Heart flabby; much fat on the outside; tissue soft and fatty; no valvular lesion, except some slight thickening of the edges of the mitral valve; heart did not retain its shape when placed on the table; no excess of liquid in the pericardium.

Liver fatty; spleen small; kidneys small and contracted. Extensive ulceration of the large intestine, most marked at the sigmoid flexure.

I have already alluded to the fact that so long ago as the time of Scultetus the use of a syringe was recommended to exhaust the portion of the effusion which was below the level of the external opening. Laennec advised the use of a cupping-glass and exhausting-syringe, with the view of draining off the last remains of fluid and of facilitating the expansion of the lung. But more recently, greatly improved suction-pumps or aspirators have been devised. Among these, the apparatus devised by Bowditch deserves prominent mention. And still more recently, Dieulafoy has modified the syringe by introducing a stopcock between the nozzle and the chamber, so that the latter may be exhausted, and then, after the point of the trocar is buried beneath the skin, the vacuum may be brought into connection with the cavity of the needle and the point be endowed with a spontaneous power of suction.

He has also devised a modification by which a vacuum is created in a graduated jar, and the cavity of the needle brought into connection with this, so that the amount of fluid withdrawn can be directly observed. This latter form has the disadvantage that in the case of large effusions it is necessary from time to time to detach the receiver (which contains about twenty fluidounces), empty it, renew the vacuum, and re-attach it. Where the collection of fluid to be withdrawn is small, and particularly if it be also offensive, this instrument enables you to remove it without exposing it to the atmosphere at all.

In attempting to estimate the relative advantages of these various methods, I would not be understood as disparaging the merits of any, whilst at the same time I would raise my voice against the unquestioning, unmeasured laudation which has been bestowed in many quarters upon Dieulafoy's apparatus. The sole object which is to be accomplished by paracentesis is the withdrawal of the effusion without permitting the entrance of air. In considering which of the above methods best secures this purpose, it is to be first observed that they all provide effectually against the possibility of the entrance of air during the withdrawal of the fluid. Let us ask, in the next place, by what forces the removal of the fluid is to be accomplished. In employing either of the two first modes, where a simple puncture with a guarded canula is made, there is no external power whatever employed. The forces which expel the fluid are—1, gravity, which leads so much of the effusion as is above the level of the external opening to escape, in seeking its level; 2, the tendency of the chest-wall, which has been greatly stretched, and of the adjoining viscera, which have been displaced, to return to their normal limits, by expelling a portion of the effusion; and 3, the centrifugal pressure of the expanding lung.

It is further evident that the first force, that of gravity, will be able to operate directly in propor-

tion to the activity of the two latter elements, since, if the lung be entirely non-expansive, the chest-wall rigid and inelastic, and the dislocated viscera fixed in their morbid position, there will be little or no escape of fluid. In other words, the rapidity and extent of the withdrawal of the effusion are measured by the promptitude and degree of the return of the viscera to their normal condition. It will therefore always be observed that the fluid, which at first flows in a steady stream, soon begins to escape by jets corresponding to the movements of respiration.

On the other hand, in the employment of either of the two later methods—Bowditch's syringe, or Dieulafoy's aspirator—we bring to bear an additional power,—that of the suction of a vacuum. In regard to the aspirator, it must be remembered that it possesses one virtue peculiar to itself, and which gives it a high diagnostic value. As there is constantly the full suction-power of the vacuum at the end of the needle as it is pushed through the tissues, it follows that the instant the fluid is reached it will be seen to enter the chamber of the syringe. Whereas, it is quite possible that, in case of a comparatively thin layer of fluid included between pleuræ thickened by plastic deposits, the trocar of a Bowditch's syringe or an exploring-needle might be passed through the liquid stratum and have its point imbedded in the thickened pulmonary pleura, and thus seriously mislead the operator. But apart from this special diagnostic value, and of its great importance in some cases I am well aware, Dieulafoy's aspirator has no advantage over Bowditch's syringe, while it has the disadvantage that, as the barrel of the syringe is small, and the piston necessarily works very tightly, the evacuation of a large collection of fluid is both tedious and fatiguing. Both instruments are, however, alike in this, that when they are used, instead of the fluid being expelled by the forces we have already considered, it is sucked out by a force which varies with the perfection of the vacuum created in the syringe, but which is in all cases quite considerable. When, therefore, all the conditions exist which render it impossible for the parts to return quickly to their normal position,—when the lung is tightly bound down, and the chest-wall rigid,—it is quite possible, despite Dieulafoy's assertion to the contrary, that an injurious traction may be exerted upon the lung by the forced withdrawal of fluid from the pleural sac.

Case III.—Double hydrothorax, associated with cancer of mamma and pleura; paracentesis thrice performed with marked relief; severe pain during use of pneumatic aspiration.

M. M., æt. 35 years, Irish, of healthy family history, was admitted to the Philadelphia Hospital on January 17, 1874. Five years ago she had a fall, striking her right mamma, and soon afterwards a swelling appeared, which ultimately proved to be a cancerous growth. The breast was removed in June, 1869; in June, 1870, the disease recurred in the cicatrix, and in August she was again operated on. In February, 1871, a third operation was performed. The general health remained fair until the spring of 1872, when dyspnoea and great weakness appeared, with dry, paroxysmal cough. There was also frequent vomiting. These symptoms

persisted until her admission, although lately vomiting has been less frequent and dyspnœa not so urgent. On admission she was anæmic and emaciated. There was a slight cachectic appearance; she also had occasional night-sweats. The right arm was weak and œdematous. There were cancerous nodules in the scar in the right mammary region; and the left mamma was much atrophied, hard, and nodular. The pulse was rather small,—100; the respirations 21. On physical examination the respiratory movements, especially the expansion of the chest, were greatly impaired; the chief movement being one of elevation and depression. At the right apex there was a high-pitched sub-tympanic note, but below the level of the second rib anteriorly there was, in the erect position, complete flatness. This was continuous around to the back at the same level. There was greatly increased sense of resistance over this flat area. In the recumbent position, resonance on percussion extended down to the third rib. The vesicular murmur was heard at the right apex, but was entirely absent below the third rib anteriorly; posteriorly it could be heard nearly down to the angle of the scapula. Vocal fremitus was almost absent on the area of flatness. Vocal resonance was audible over the whole of the back; along the vertebral gutter out to the angle of the ribs there was ægophony, while farther out there was quavering, feeble bronchophony. There was no downward displacement of the liver. The apex-beat of the heart was under the left nipple. On the left side there was complete dullness below the fifth rib.

On Friday, February 26, a No. 2 aspirator-needle was introduced through the sixth right interspace on a line with the middle of the axilla. A clear, reddish-yellow, serous fluid escaped freely through the needle under the use of the aspirator; at first the withdrawal of the fluid was attended only by a slight hacking cough, but after three pints had been withdrawn the patient began to complain of great pain under the sternum, with a sense of dragging there; this was increased on respiration, and grew worse with each additional use of the pump. The entire amount of fluid withdrawn was Oijss (56 f℥), when the operation had to be discontinued, owing to the suffering it caused. The pulse and breathing were accelerated immediately after the operation, owing to pain and excitement. The pain continued severe for ten minutes. The following day the patient felt much relieved; the breathing was easier, though there was still but little motion of the right side; there was still flatness up to the second rib over an area extending about one and a half inches to the right of the sternum; on the line of the nipple there was resonance down to the third rib anteriorly, and down to below the angle of the scapula posteriorly. Respiratory murmur was feeble below the third rib anteriorly, and below the angle of the scapula posteriorly; above these levels it was clear and strong, mixed with coarse creaking and dragging friction-sounds, which were heard most distinctly over the scapular region. There was distant, feeble respiratory murmur with prolonged expiration heard almost to the base of the thorax. The condition of the left side was unchanged. There had been no elevation of temperature.

On March 15, although the patient's condition continued relieved, the evidences of effusion in the right thorax were so positive that the same aspirator-needle was again introduced through the same spot. This time the pump was not used, but an india-rubber tubing was attached to the needle, so that the fluid might escape merely by gravity and the pressure of the expanding lung. The same character of fluid escaped immediately through the needle, but so slowly that it became evident that the lung was unable to expand. It flowed at the rate of about f℥i per minute, and, when f℥xvi to xx had escaped, ceased entirely. The patient experienced

none of the peculiar dragging pain which had attended the first tapping, and expressed herself as somewhat relieved. The operation was not followed by a single disagreeable symptom, and there has since been no increase of effusion on that side.

In the early part of May the effusion in the left pleural cavity had increased so greatly as to demand operative relief. Paracentesis was accordingly performed in the same manner as upon the right side (Dieulafoy's aspirator being employed), and about seventy fluidounces of clear serum were withdrawn. The operation was attended with but little pain, and has been followed by no demonstrable reaccumulation of fluid, although the evidences of intra-thoracic cancerous disease are developing.

It must be further asked, in connection with this point, how much advantage attaches to the entire withdrawal of the effusion. It has been held by some that it is undesirable to do so, but I confess to being unable to perceive any good reason for fearing to do it in cases where it is evident, by the return of pulmonary resonance and the development of the vesicular murmur, that the lung is expanding freely to occupy the place of the effusion. In such cases it is undoubtedly possible to withdraw the accumulation by the simple canula, as described. In other instances, where the effusion is serous, but yet the lung is incapable of fully expanding by the mere pressure of the atmospheric air entering its tissue, it may be of service to supplement this by the force of aspiration. But I have not observed in such cases any disadvantage from allowing a portion of the effusion to remain, since it has often been possible, after the excessive distention was removed, to secure the absorption of the remainder as the lung gradually expanded.

In fine, the result of my own experience has been that the greatest value of the "aspirator, with the previous vacuum," in cases of pleural effusion, is a diagnostic one; that in cases of large effusions, when the lung is free to expand, the effusion can be easily, safely, and successfully withdrawn by a simple guarded canula; that in cases where the inability of the lung to expand prevents free escape of the fluid through the canula, it is desirable to employ an exhausting syringe, unless its use is attended by such severe pain as to indicate excessive tension upon the pulmonary tissues or upon organized adhesions.

(To be continued.)

CASE OF OVARALGIA.

BY W. S. MAXWELL, M.D.

MRS. B., aged 32, married, mother of three children, had been suffering from metrorrhagia for eight weeks, the result of an abortion, for which I was treating her.

September 17, 1873, I was called to see her in great haste. Found her suffering intensely with pain in the region of both ovaries, with shooting pains extending to the perineum, back, and shoulder. The pains were of an intermittent character; there was tenderness upon pressure over both ovaries, nausea, constipated bowels, tongue clean, no fever, temperature normal.

Mrs. B. was subject to facial neuralgia, and was out the day before in the rain. Taking all things into consideration, I concluded that she was suffering from neuralgia of the ovaries.

Treatment.—Morphia in one-quarter grain doses was injected hypodermically every hour until a grain had been given, before relief was obtained. The relief was transient; as soon as the effects of the morphia wore off, she was as bad as ever. An enema was given and repeated several times, but there was no movement from the bowels. Nausea was finally quieted by all-spice tea.

Sept. 18.—No better. Continued the morphia hypodermically. Ordered

R Quiniae sulphas, gr. xxiv;

Morphiæ, gr. i.

Ft. pil. xii.

Sig.—Two pills every four hours.

Sept. 19.—Much better; bowels were moved; she slept several hours.

Sept. 20.—Better; some appetite.

Sept. 21.—Worse than she had been; no change in the symptoms. Used morphia hypodermically to give relief. Ordered

R Quiniae sulph., ðiv;

Morphiæ, gr. iv.

Ft. pil. xl.

Sig.—Two pills every four hours.

Sept. 22.—Better; continued to improve.

Oct. 1.—Able to be up; the metrorrhagia was cured.

June 3, 1874.—At this time Mrs. B. is enjoying excellent health.

ANOMALY OF THE PHRENIC NERVE.

BY C. T. HUNTER, M.D.

IN the winter of 1873, while dissecting the lateral region of the neck of a white male subject, I found an exceedingly rare and interesting anomaly in the course and relations of the right phrenic nerve.

In tracing the nerve to its apparent origin I discovered that it arose from the anterior branches of the third and fourth cervical nerves,—the normal arrangement. In addition, however, it received a communicating branch from the axillary plexus, which branch joined the phrenic nerve at a point immediately above the subclavian vessels. The course of the phrenic nerve was almost vertically downwards from its origin along the outer edge of the scalenus anticus muscle, and when it reached the base of the neck, instead of crossing the first part of the subclavian artery and passing between the artery and the vein, as in the normal distribution, it took its course in front of the third part of the subclavian vein, and descended into the thorax behind the right internal mammary artery, thence to its normal position on the outer side of the right vena innominata and superior vena cava.

On examining the left side of the subject's neck I found the phrenic nerve in its normal position.

This irregularity in the course of the phrenic nerve I have not found recorded in any of the American or English works on anatomy or surgery: therefore I infer that it is very rare, and that the surgeon is not likely to meet with it in the deligation of the subclavian artery at the point of election—viz., the third part.

NOTES OF HOSPITAL PRACTICE.

BELLEVUE HOSPITAL.

SURGICAL CLINIC OF PROF. JAMES R. WOOD.

Reported by FRANK WOODBURY, M.D.

OPERATION FOR THE RADICAL CURE OF INGUINAL HERNIA.

GENTLEMEN,—The subject to which I will invite your attention to-day is one of more than ordinary importance. From the days of Hippocrates to the present the treatment of hernia has been the objective point to which not only the best minds of the profession have been directed, but it has also engaged the attention and furnished lucrative practice for a host of empirics, male and female.

A hernia may be defined as a protrusion of some of the contents of the abdomen through its parietes, at other than the natural outlet. I have seen the bowel prolapsed as far as the sigmoid flexure, but this is not a hernia within the limits of our definition. I will not dilate upon the varieties of hernia, but will state that, according to its location, it is called diaphragmatic, umbilical, inguinal, femoral, ischiatic, or lumbar, and may consist of bowel and omentum, forming an enterocele, or simply of omentum, constituting an epiplocele. I will postpone the complete discussion of this subject, reserving it for a didactic lecture at the college. You may judge of the extent of this affection from the fact that one person out of every thirteen that you meet is the subject of hernia; and a surgeon in large practice has these cases coming to him every day, so that it is absolutely necessary for you to understand its diagnosis and treatment. Your books speak of external and internal abdominal rings, inguinal canal, etc., but you cannot find them in the ordinary subject in the dissecting-room, because they are part of the pathological condition, and are formed by the gradual yielding of the cellular tissue before the descending bowel: its cure consists in restoring the bowel to the abdomen and obliterating the canal.

Some of the operations that have been performed for its radical cure are barbarous in the extreme. Men and women travelled about the country performing for its relief excision of the scrotum, or its strangulation by a ligature to induce sloughing, sometimes including in the ligature both testicle and scrotum of the affected side; they even bared the spermatic cord and ligated it, nerve and all; but the favorite operation was castration. It is said that Paracelsus, a notorious quack, was in the habit of feeding his dogs upon the testicles so obtained. To be sure, these operations caused suffering and frequently death, but they were not greatly improved until a comparatively recent period. The actual cautery was even recommended and employed to excite adhesive inflammation of the walls of the canal and thus cure the hernia, as it had long been employed to arrest hemorrhage. Think of thrusting a hot iron into a stump to stop bleeding from a femoral artery and smaller points of oozing after an amputation, or of pouring upon it boiling pitch or oil, and this without an anæsthetic! Yet this was done until the fifteenth century, when Ambrose Paré introduced the use of the ligature.

Although great improvements had taken place in the art of medicine, yet it was not until 1836 that the first rational operation for the radical cure of hernia was devised. Gerdy then recommended invagination of the scrotum by the surgeon's index-finger into the canal and confining it there by two points of interrupted suture, and through its anterior wall; the pouch is then washed with spirit of ammonia, to cause adhesion of the adjacent surfaces. This was a great advance, but was

still imperfect, because the internal ring being still patulous the hernia was not cured, but merely converted into an incomplete hernia or bubonocoele. To remedy this, Bonner, in 1837, recommended passing acupuncture pins through the neck of the sac, and thus obliterating it; but this plan is not so effective as that of Gerdy, which I have frequently employed, inserting into the canal a sponge saturated with liquor potassæ, spt. ammoniæ, or sol. corrosive sublimate, with good result.

The following year a man in Bonn on the Rhine, Wutzer, devised the instrument I now exhibit. It is composed essentially of three pieces,—a wooden cylinder, a curved needle, and a wooden cover which clamps upon the cylinder. The cylinder is passed into the invaginated pouch, and by means of a screw a steel needle, which is concealed near its end, is made to project through the anterior wall of the canal, and is received into a fenestra in the external blade; the instrument then remains in position at the pleasure of the surgeon. The value of this operation consists in the fact that it obliterates the canal high up and immediately in front of the internal ring, which, as you know, is half-way between the anterior superior spinous process of the ilium and the spine of the pubes. Good results may be obtained by this means; but, whatever operation you adopt, be careful not to include the gut in the embrace of the instrument, and not to cause peritonitis by inducing a too high degree of inflammation. This instrument was modified, but not altered in principle, by the addition of another needle, by an eminent man whose services in teaching we gained shortly after the war, and who was until lately in the enjoyment of a large practice in this city. I refer to the late Prof. Nott, of Mobile, who enjoyed the esteem of the entire profession, and whose recent death excites general regret.

Many other instruments have been devised. I here show you Riggs's improvement upon Armsby's needle and canula, which may be cited as the most prominent.

Other operations have been recommended, such as the procedure of Velpeau, who cut down upon the sac and injected an irritating fluid to cause adhesion. This was improved by that great man, Prof. Pancoast, of Philadelphia, who used an injection of tincture of iodine through a canula without exposing the sac, first placing a finger over the internal abdominal ring to prevent the fluid from flowing into the peritoneal cavity. This I consider about the best operation of all.

The question will be asked by your patients, "Can I be cured by an operation?" My experience upon this point is that in the majority of cases the hernia returns; and I have seen more of these cases, and performed this operation perhaps more frequently, than any other living surgeon. I do not say this boastfully, but I always endeavor to tell you the simple truth as familiarly as if you were gathered around my own fire-side. You should answer, then, that it will probably recur unless the patient continue to wear a truss.

To the case before you there is attached a point of especial interest. About seven weeks ago he came here with an irreducible hernia, incarcerated but not strangulated. In such cases, never think of subjecting your patient to the risk of an unjustifiable operation. Where the gut is strangulated, you have no choice: you are obliged to do your utmost to save the patient's life; but never operate where there is simply an incarceration, a principle which is well illustrated by the subsequent progress of this case. He applied for an operation, which he had been told was necessary. This we refused, preferring to postpone it until more urgent symptoms were present. We kept him upon his back in bed, and at the end of six weeks there was a spontaneous reduction of the hernia. This shows that ill-timed operations are injurious. I never operate upon a case of fistula in ano without first inquiring into the patient's family

history, and auscultating his chest, because where it complicates phthisis we find that nature has provided this as a sewer to drain from the blood some effete material; but if the surgeon injudiciously dries this up, he injures his patient. A fistule being exceedingly annoying and disagreeable, we are sometimes obliged to operate even in cases of phthisis; but I never do so without placing, at the same time, an issue-pea at the insertion of the deltoid, to supplement nature's drain.

To-day we propose to perform the Wutzer operation, and may make a cure, although the canal is quite large. The trouble is generally reproduced by the descent of the bowel by the side of the adhesions.

No anæsthetic is necessary. The instrument is applied as described, and held in position by a Spica bandage. This is to prevent the instrument from tearing off the insertion of the external oblique muscles, which, however, might prove advantageous in some cases, by encouraging adhesion, as an operation has been recommended by a namesake of mine, Prof. Wood, of London, in which a delicate knife is made to refresh the columns of the ring, which are then approximated by a ligature. This operation is very popular in England. We will permit the instrument to remain in position from eight to ten days.

GANGLION OF WRIST.

In this case of ganglion, I wish to show you the use of the aspirator of Dieulafoy. By this instrument we can with perfect safety evacuate a pleural effusion, or go in over the pubes to tap a distended bladder which cannot be entered by a catheter on account of enlarged prostate or impassable stricture. We can evacuate tumors and abscesses, even draw off the gas from a strangulated hernia, and assist its reduction. We can even diagnose a malignant tumor by plunging it into the growth and examining the juice by the microscope, and, if we find the cells, we can also make a prognosis.

A cystic tumor in this situation may exist in the cellular tissue, or in the theca of the tendons, or communicate with the joint, and contain synovial fluid. This tumor resembles the affection known as house-maid's knee, in which there is effusion under and around the patella, caused by inflammation of the mucous bursa in this situation from constant kneeling. This also sometimes occurs in ministers, especially after a camp-meeting.

Having evacuated this cyst of a clear, glairy fluid, the subsequent treatment will be by local pressure and passive motion.

CASES OF OVARIOTOMY.

BY WASHINGTON L. ATLEE, M.D.,

Philadelphia.

CASE 247.—Ovarian tumor mistaken for pregnancy—Both ovaries removed—Incision four inches long—Omental, intestinal, uterine, and pelvic adhesions—Death on the fourth day.

January 9 and 14, 1872, I examined Mrs. G. W. B., of this city, in consultation with Dr. W. Lemuel Atlee. She was 28 years old, had first menstruated in her eighteenth year, and had always been regular. She was married in 1864, and had never conceived. In the summer of 1869 she was quite ill for several weeks with great gastric distress, followed by considerable emaciation. The following January she noticed some fullness of the waist and abdomen, and in the spring of 1870 she had a similar attack, accompanied with excessive vomiting. The enlargement increasing, her physician was positive that she was pregnant. In July she intended to have left home, but her medical adviser forbade it, fearing that she might be confined in the cars.

He had engaged her nurse, and the baby-clothes were all made.

At the time of my visit the patient's abdomen was much larger than a pregnant woman's at full term. It was pretty uniform in shape. There was dulness on percussion everywhere, except over the right lumbar region, where it was resonant. There was some resistance to pressure over the right inguinal region, but elsewhere the abdomen was elastic. Fluctuation was distinct. She was then menstruating, and the os tincæ had a velvety feel. The uterus was central. In front of it a tumor can be felt in the superior strait of the pelvis. There was numbness of the left thigh, but no swelling of the lower extremities. She was considerably emaciated. Deep inspirations did not affect the tumor, in consequence, probably, of its large size. Contraction of the recti muscles caused an oval projection between them.

Diagnosis.—Tumor of the left ovary, consisting of one large cyst with multilocular deposits in its walls.

The operation was performed January 17, 1872, with the assistance of Drs. W. Lemuel Atlee, Burpie, Mears, Hoffman, Longshore, and Buckman. An incision four inches long was made down to the cyst. No parietal adhesions were present. The cyst was tapped, and thirty pints of transparent fluid were removed. The fluid resembled urine tinged with bile, having a dark brownish-yellow color, and was loaded with cholesterol. After emptying this large cyst, multilocular masses were felt in the abdomen. These were punctured through the wall of the large cyst, but no fluid escaped from them. They were afterwards broken up, so that the whole upper portion of the tumor could be drawn out of the abdominal cavity. The omentum was now seen to be spread over the right wall of the tumor and adherent to it, and several inches of intestine were adherent to its posterior wall, while the lower portion of the tumor was strongly adherent to the basin of the pelvis. These adhesions were overcome,—the pelvic by means of enucleation. In doing this, an additional cyst, as large as a small orange, was raised from the right side of the pelvis, and attached closely to the large tumor. This proved to be the right ovary, and in breaking up the strong adhesions its pedicle was torn across, giving rise to an arterial jet of blood, which was controlled for the time by the fingers. The large tumor was still attached to the whole posterior surface of the uterus, from which it was stripped. It was also adherent to its own pedicle throughout its whole extent, and from which it was separated. The pedicle, when detached, was four or five inches long, very vascular, and contained a hypertrophied Fallopian tube. For the present a ligature was applied to it, so as to secure all its bleeding vessels, and the tumor detached.

The adhesions were very vascular, and numerous vessels were throwing off blood. Five, altogether, were secured by ligation, two of them on the posterior face of the uterus. The clamp was substituted for the ligatures on the pedicle. The ragged, bleeding extremities of the omentum were secured in one ligature, and its stump fixed in the upper angle of the wound. The pelvis and abdomen were now carefully cleansed, and the wound closed by four sutures. The patient bore the operation well. There was some vomiting, but no flagging of the pulse.

The tumor and contents weighed thirty-five pounds. Died from exhaustion on the fourth day.

TRANSLATIONS.

THE TREATMENT OF TYPHOID FEVER BY THE EXTERNAL USE OF WATER (*Allgemeine Militär. Zeitung*).—Regimental Surgeon Lederer during the past five years has treated many cases of typhoid fever with cold water, and at a meeting of the Society of the medical officers of the garrison of Vienna in April of this year he gave the results of his experience. After calling attention to the prominent rôle played by typhoid fever among the diseases incident to military life, and noting the high rate of mortality which attended it in the late civil war, he proposed the following three queries. 1. Are the results obtained from the cold-water treatment better than those from other modes? 2. Can this treatment be advantageously carried out in military hospitals? 3. What symptoms should be regarded as indications for the use of the cold-water treatment? The extreme hydropathists would give an unqualified affirmative to the first query, for they assert that by their mode of treatment the mortality is greatly reduced. Some of them even assert that water is a specific in the treatment of this fever, and that if the patient is properly treated at an early stage the disease can be cut short. From his observations, Lederer does not look upon water as possessing this specific power, and he thinks that the trials of this treatment have not as yet been sufficiently numerous to warrant the formation of conclusions as to its value. He is convinced, however, that under this treatment the disease runs a milder course, and that some of the graver symptoms may not manifest themselves. The intense headache which is sometimes one of the initial symptoms may vanish after the first baths. So, too, the delirium which commonly appears at the end of the second week may by the use of baths be so greatly modified as to be of a very mild type, or even entirely done away with. In support of this he adduces several cases in which the rapid transition from a state of wild delirium to quiet after the use of a few baths was most marked. The influence upon the return of the appetite is also marked; the tongue becomes cleaner, and the diarrhœa is not so excessive. The influence of the bath, too, in tending to produce sleep, is most marked. Bed-sores are not so apt to occur, and convalescence is more speedy. The advantages of the cleanliness promoted by the frequent use of the bath upon the general hygiene of the ward can be readily understood. As to the methods to be employed, Lederer thinks that packing the patients in damp sheets is not suitable to military hospitals, since the frequent changes of the cloths which are required call for the services of too many nurses. He therefore does not use this method, nor the one in which the surface is sponged off, but advocates the use of the cold bath, either with or without the douche. The patient, when the temperature in the axilla is above 101.5° Fahr., is placed in the bath, and a greater or less amount of water is poured upon him as the cerebral symptoms are more or less pronounced. These applications are made from 7 A.M. until 12 at night, at intervals of three or four hours, the temperature of the bath varying from 68° to 77° Fahr., that of the douche from 54° to 60° Fahr.

In answer to the third query, as to the indications for the use of the bath, he thinks that every patient with typhoid whose axillary temperature rises to 101° or above is a fit subject for this treatment, and that the earlier the cold bath is used the better it will be borne, and the more promising are the results to be looked for. If symptoms of cerebral involvement are present, the indications are still more pressing. He thinks that more care is to be exercised in the use of the bath upon such patients as are very restless, or have marked hy-

AGREEABLE PURGATIVE.—

Aquæ, fʒii;
Syr. orgeat (or Curaçoa), fʒss.—M.

peræsthesia of the skin, and if the first bath is not well borne in such a case it should not be repeated. If complications arise during the course of the disease, such as infiltration of the lung or peritonitis, the baths must of course be discontinued. In conclusion, then, he thinks that this mode of treatment is of advantage in many cases, that it tends to diminish the risk of injury to delirious patients, that the risk of the occurrence of bed-sores is lessened by it, and that its use tends to limit the spread of the disease. W. A.

THE TREATMENT OF ERYSIPELAS WITH HYPODERMIC INJECTIONS OF CARBOLIC ACID.—Dr. Aufrecht (*Centralblatt für die Med. Wissenschaften*), having had under his care during a short time several cases of erysipelas in aged persons, after comparatively slight injuries, all of which terminated unfavorably, was induced to try carbolic acid in the treatment of this disease. If it is true that erysipelas in traumatic cases such as these is a consequence of the entrance of organic bodies into the subcutaneous cellular tissue and their proliferation there, and if carbolic acid possesses the power of destroying these germs, or at least of rendering them innocuous, the acid must be able to prevent the spread of the disease, and thus to some extent reduce the danger. To convince himself that the hypodermic use of carbolic acid was innocuous, Aufrecht made experiments upon himself with a solution of the strength of one per cent., and found that its use was attended by no unpleasant consequences. He soon had an opportunity of proving the efficacy of this treatment upon two patients,—the first a woman, aged 56 years, with erysipelas of the fore-arm and hand, upon the latter of which was a small cut; the second was a man aged 82 years, with erysipelas of the leg, about the scar of an old ulcer which had reopened. In the first of these cases five, and in the second four, injections were made. The injections were made into the sound tissue upon the proximal side of the erysipelatous area, and the disease spread no farther in that direction. The good effect of the treatment was, however, more strikingly manifested in the diminution of the temperature and the frequency of the pulse, and in the improvement of the general condition. The erysipelatous swelling and redness soon became less, but remained noticeable for a day or two after the injections were made. In both cases convalescence went on without interruption. W. A.

HEMORRHAGE OF THE LUNGS AS A RESULT OF INJURY OF THE BRAIN.—Prof. Nothnagel, of Freiburg, states that among the characteristic alterations which follow lesions of a particular portion of the superior surface of the cerebrum of the rabbit, one of the most pronounced is hemorrhage into the lung-tissue, which is often so excessive that the entire lung is engorged with blood. Brown-Séquard observed an analogous phenomenon resulting from injury not of the convexity but of the base of the brain. By a similar manipulation, a meningitis can be caused, which, as a rule, is bilateral, and, when only upon one side, is usually seen on the uninjured hemisphere.

Nothnagel considers that it is impossible that the occurrence of this meningitis should be but a coincidence, and promises further investigation of the subject. W. A.

INFLUENCE OF THE SPLANCHNIC NERVE UPON THE MOTION OF THE INTESTINES.—S. V. Basch (*Centralblatt*) concludes from his investigations that the splanchnic nerve does not properly cause a cessation of the intestinal motions. It restrains these movements only inasmuch as it, being a vaso-motor nerve, eliminates the motor irritation from the arterial circulation.

The cessation of these movements, which is due to

carbonized blood, must also be regarded as a consequence of the irritation of the vascular nerve-centre, which often remains in operation after section of the splanchnic nerves, but is eliminated by section of the medulla oblongata. Nicotine acts in the same way—*i.e.*, after causing some motion for a short time, causes a cessation of the peristaltic motion. W. A.

TERMINATION OF NERVE-FIBRES IN JOINTS.—Krause, of Göttingen, has found that sensory nerve-fibres end in the synovial membrane of the joints of the human finger by means of characteristic terminal bodies. From one to four nerve-filaments, after numerous anastomoses, become lost in oval bodies of varying size, the largest of which, however, can be seen with the naked eye. Bodies which are entirely similar are found in some of the lower animals, but they vary somewhat in size, and may be of a round instead of an oval form. W. A.

THERAPEUTIC NOTES.

CROTON-CHLORAL IN FACIAL NEURALGIA (*The British Medical Journal*, May 23, 1874).—Dr. F. B. Lee reports the case of a lady, æt. 32, who had suffered for years from attacks of facial neuralgia, had had several teeth extracted, had been blistered behind the ears, and had tried numerous other means without avail. He prescribed croton-chloral in three-grain doses every four hours. After the third dose perfect ease was experienced, and, although three months had elapsed, there had been no return of the disease.

NITRATE OF URANIUM IN DIABETES MELLITUS.—Mr. Kennedy details (*London Lancet*, June, p. 835) a case of diabetes, in which, after failure of skim-milk and other therapeutic measures, rapid improvement took place during the administration of the nitrate of uranium. One-sixth of a grain, gradually increased to a third, was given three times a day, dissolved in water.

CHLOROFORM AS AN INGREDIENT OF INJECTIONS FOR HYDROCELE.—Dr. Lubin (*L'Union Méd. de Canada*), observing the frequent lumbar pain consequent upon the use of the ordinary injections in this affection, was led to use a formula similar to the following:

R Tinct. iodinii comp., fʒii;
Chloroformi, fʒiiss.

In a number of cases in which this mixture has been used, no pain whatever followed its injection.

TOPICAL APPLICATION IN PAINFUL DENTITION.—

R Syrup of tamarinds, ʒiiss;
Infusion of saffron, ʒii;
Honey, ʒiiss;
Tinct. (essence) of vanilla, gtt. iv.—M.

Rub gently over the gums with the finger or rag. An application of a similar character is the following:

R Saffron (powdered), 4 to 6 grs.;
Honey, 2 to 3 drachms.

Glycerin may be substituted for the honey.

SOOTHING APPLICATION IN HERPES ZOSTER.—

R Collodion, ʒi;
Morphiæ muriat., gr. viij.—M.

To be painted over the vesicles without breaking them open.

EXPULSION OF THREAD-WORMS.—The oxyuris vermicularis, or seat-worm, may be readily dislodged from its favorite habitat in the rectum by the injection of two to three ounces of ol. morrhue, repeated once or twice.

PHILADELPHIA MEDICAL TIMES.

A WEEKLY JOURNAL OF

MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY

J. B. LIPPINCOTT & CO.,

715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, JULY 4, 1874.

EDITORIAL.

EUTHANASIA.

UNDER the heading of "Whither are we Drifting?" we entered some time since an indignant protest against the suggestion or opinion of Dr. H. J. Bigelow, of Boston, that physicians should put an end to such patients as were apparently about to suffer a lingering death. We have heard of this being done in this city. We have, indeed, been told of a case in which a patient, receiving a dose of opium intended to kill, survived for two years the villany of the physician and the mortal disease. We do not know whether these things are or are not so. But we do hope that any physician who is guilty of such practice will get what he deserves, and what the law, in that it says, "whoever accelerates death causes it" (Taylor), certainly allots,—the penitentiary for manslaughter, if not the gallows for deliberate murder.

We write this, and at this time, because there has recently appeared in England an essay, entitled "Euthanasia," written by Mr. S. I. Williams, Jr., and published under the auspices of a Mrs. Crayshaw, who is said to be the wife of one of the millionaire iron and coal owners of Wales. In this publication the right or rather duty of suicide is set forth, the claim being "based on the paramount duty of doing all that is in our power to lessen the amount of physical suffering in the world."

Morally, this reasoning, acute and seemingly logical as it may be, is to us simply satanic. If it justifies suicide, much more does it condone

infanticide, murder of the old, sick, or deformed, and other equally pleasant customs of the ancients.

As, however, the abstract discussion of moral questions is somewhat out of the province of this journal, we would scarcely have noticed this pamphlet had it not been for certain sentiments which are embodied in the following quotation :

"That in all cases of hopeless and painful illness, it should be the recognized duty of the medical attendant, whenever so desired by the patient, to administer chloroform, or such other anæsthetic as may by-and-by supersede chloroform, so as to destroy consciousness at once, and put the sufferer to a quick and painless death; all needful precautions being adopted to prevent any possible abuse of such duty, and means being taken to establish, beyond the possibility of doubt or question, that the remedy was applied at the express wish of the patient."

Without further comment, we express the hope that if Mr. Williams or his supporters ever desire to reach this euthanasia, even the wealth of a Mr. Crayshaw will be unable to lead any physician to prostitute his office to that of an executioner.

PUERPERAL FEVER.

PUERPERAL FEVER is certainly very prevalent in some parts of New York city, and also, we believe, in this city. According to the official reports, however, in New York there have been this year, to June 6, two hundred and twenty-four deaths from such cause, whilst in the same period of last year there were two hundred and sixty-one fatal cases. But as average human nature is the same everywhere, and as we know that the official statistics in this city are worse than useless, we judge the figures just quoted are of no value. This does not arise from any fault of the officials concerned, but from the untrue death-certificates handed in by attending physicians. Thus, one prominent medical gentleman of this city was called in consultation during a recent month to no less than eight cases of puerperal fever, seven of which proved fatal, and yet during that month there was not a single death from such cause reported. During the same period another obstetrical friend was cognizant of some twelve cases, distinct from those already alluded to,—a large proportion ending fatally. If we were omniscient, no doubt this list could be greatly lengthened. But the evidence is sufficient for our purpose. A reputation for having cases of puerperal fever is such an evil possession that obstetricians not only do not covet it, but actually loathe it, and a euphemism is but a mere stroke of the pen.

However these things may be, it is certain that

during the spring there has been in Bellevue Hospital a most serious epidemic. In the winter there were a few very virulent cases, but in April a number of women were attacked almost simultaneously. Vacating the portion of the building previously occupied was tried, but after a fortnight the epidemic reappeared in a most virulent form,—ten out of the fourteen patients attacked dying. The Commissioner of Charities, at the suggestion of the physicians, then had all the pregnant women removed to a new, one-story wooden building on Blackwell's Island. Since this change the epidemic has very greatly abated, although several fresh cases have occurred.

In regard to the entire number of persons attacked, the records of the hospital show that from January 1, 1874, to June 1, there were fifty-two cases, with twenty-eight deaths from the disease.

PROCEEDINGS OF SOCIETIES.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

A CONVERSATIONAL meeting was held Wednesday, March 25, 1874, at 8 o'clock P.M.

The PRESIDENT, DR. W. L. ATLEE, in the chair.

DR. W. B. ATKINSON called the attention of the Society to the epidemic at present prevailing. The eruption seemed to be in many instances a combination of that of measles and scarlatina. In several cases he had recognized a true diphtheritic deposit in the throat. All had more or less sore throat, and some had, in addition, brain-symptoms like those of cerebro-spinal meningitis. The eruption is prolonged, and does not disappear as is generally the case in rubeola or scarlatina.

One house, in a locality otherwise healthy, seemed particularly marked by the tendency, and had acted as a focus whence the disease had radiated to other cases. On careful investigation, he had been unable to find any cause, as defective drainage or the like. He has encountered cases of cerebro-spinal fever, so called, for the last six or eight months. In fact, this has been wide-spread through the country, and does not appear to be confined to any special district. As showing a tendency to blood-poisoning, he had recently met with several cases of purpura.

DR. M. O'HARA had seen a number of cases of measles recently. Three of them undoubtedly had gone through an attack of measles before; in one case only six months ago. He had seen no case like those mentioned by Dr. Atkinson, but the description tallied somewhat with the case of his own child, who died last July of cerebro-spinal fever, and he would like to know of the doctor if there were any signs whatever of affection of the spinal centres. Except a slight retraction of the nuchal muscles, no distinction could be made between this case and scarlet fever, or, later in the case, between it and mixed scarlatina and measles, with complications of a diphtheritic character. During the third week, in which the child died, it showed evidently that it had been all the way through a case of cerebro-spinal meningitis. He desired to know of Dr. Pepper what was his experience as regards second attacks of measles.

DR. W. PEPPER had seen several cases such as were spoken of by Dr. Atkinson. Some were ordinary measles, contagious, rash appearing on the fourth day, and terminating well. In a few others there was tonsillar and faucial trouble; the papules at the same time were more distinct, with thickening and infiltration of the skin. He had seen a few cases apparently of mixed scarlatinous type. In one case, a child of seven years of age had played with another who had had malignant measles. In her case there were prodromes of catarrh. There was a typical scarlatinous eruption about the neck and one thigh. The throat was sore, with white pseudo-membranous exudations on both tonsils. On the other portions of the body the eruption was rubeolous in character. There was no albumen in the urine. The pulse one hundred and fifty. Temperature high. Swallowing difficult. The cases to which Dr. Atkinson referred were apparently analogous to this last. He believed that both poisons coexisted in the case detailed above, and perhaps in others. There was very little pure diphtheria, but a large amount of scarlatina, in the city. The cases of Dr. Atkinson were possibly measles, modified by the scarlatinous poison. He had not met with the prolonged eruption. It sometimes occurs. Dr. P. replied to Dr. O'Hara that, in his opinion, second attacks were more common in measles than in any other eruptive fever.

DR. PRALL asked Dr. Atkinson if petechiæ occurred at the close of the regular eruption. He had seen only a few cases. He had seen three cases of second attacks of measles. In one case which recovered, petechiæ appeared, and continued two weeks. There were no head-symptoms or sore throat.

DR. G. HAMILTON said he had not been aware until this evening of the existence of such an epidemic as that alluded to. The general health of the city is exceptionally good. Measles prevailed throughout the city, so far as he had seen, in a mild form, and the reports of the weekly mortality showed only a small proportion of deaths from this cause. When measles and scarlet fever occurred simultaneously, as an epidemic, each disease seemed capable in some cases of being modified by, as it were, a sort of assimilative action exerted by the other. As members are present from different and remote parts of the city, it might be well for them to state whether cases similar to those seen, more especially in the southwestern portion, have occurred in their respective localities.

DR. T. MCKEAN had seen a number of cases on New Market Street near Vine Street. The population was very much crowded there. He had seen three and four cases in one house. There was in some cases throat- and spinal-trouble.

DR. W. M. WELCH remarked that he had under his care at the present time cases both of scarlatina and measles; but in no case were the two diseases combined. He had observed nothing unusual in either of the diseases, except that two of the cases of measles were second attacks. These patients were brothers; one of whom, a child ten years old, had undergone a previous attack at the age of one or two years; the other, a child aged seven years, had suffered from a previous attack three years ago, at which time the former child was exposed to the contagion without contracting the disease.

DR. W. PEPPER then read a paper on "The Operative Treatment of Pleural Effusions."

By request, the Secretary read from the *American Journal of the Medical Sciences* for January, 1855, p. 68, the notes of a case communicated to Dr. Bowditch, of Boston, by Dr. Washington L. Atlee, of a large collection of pus in the left pleural cavity, which had been successfully treated by repeated injections of iodine.

The case was reported by Dr. Bowditch to "The Boston Society for Medical Improvement," and subsequently by Dr. Morland, the Secretary of that association, in the above journal.

After the reading of the report, Dr. Atlee stated that although this case of pyothorax had occurred as far back as 1850-1, the patient, an extensive paper-manufacturer, is still living, in robust health, having required no medical attention since that time.

REVIEWS AND BOOK NOTICES.

UNIVERSALITY OF THE HOMŒOPATHIC LAW OF CURE.

By CHARLES NEIDHARD, M.D. Second Edition. Boericke & Tafel.

This little brochure having been sent to the *Times* for notice, we have read and re-read it carefully: at first with attention, then with amusement, and finally with astonishment. There are some things which, in themselves insignificant, become significant from their origin. When Napoleon writes, the world reads carefully, though the Napoleonic utterances be but twaddle. The author of the present pamphlet is a very Pharisee of the Pharisees among his brethren, and commands a large and lucrative practice among the best classes of our citizens. Yet, when he opens his mouth, what manner of pearls fall from it!

The man who could in cold blood put forth such utterances as those in this book is beyond the reach of the artillery of the reviewer; no cudgel of argument so heavy as to beat down his guard of ignorance; no arrow of sarcasm so swift and sharp as to pierce his panoply of non-perceptive power. Shall the fool perceive his folly, or shall he that was born blind see? Under the circumstances, we can but let Dr. Neidhard out of his own mouth convict himself, and without further comment offer some choice selections, which reveal the evidence upon which modern homœopathy relies for the proof of its tenets. We are sorry that want of space will not permit our extending these quotations.

"The best thief-catchers and detectives are those who formerly have been engaged in the same business,—that is, have been thieves.

"Political rings, united for the purpose of plunder, are best cured by similar rings united for the purpose of honest reform.

"A young gentleman afflicted with rheumatism and a severe cold in the breast was on the eve of being united to a beautiful young lady. In order to be cured, and before his marriage, he went South. . . . All the medical gentlemen with whom he consulted told him he could not live. Weary of physicians, he again went home to die. He was carried from the boat to the hotel more dead than alive. On the sixth day after his return he learned that his betrothed had been married a day previous to another, thinking her lover could not survive. All the friends of the deceived lover thought that this would prove fatal at once in his then state of health, but, instead of their fears being realized, in a week from the day of the reception of the unsuspected news he arose from his bed and rapidly recovered, and in less than a month was as well as ever. Disappointed love can cause consumption and rheumatism, but, when you have it, it may also cure it—a true homœopathic cure.

"Thus the doctrine of miasmatic diseases and homœopathy occupy the same platform. If one not acclimated or accustomed to a certain malaric effluvium, and inimical to his nature, is exposed to it, he falls sick, in the same way as he is cured by another agent similar to the nature of the miasma. This latter will probably be some plant growing in the neighborhood, or the

poison of some animal luxuriating and arriving at its full growth in the very marshes from which the disease is generated. Do you think that the plants which cure the malignant fevers of miasmatic districts could grow on high mountains?

"A vicious boy who pokes his umbrella into everybody's side is cured by letting him stand in a corner with an immense umbrella over his head until he is tired. Another who bends his head under the table to catch at boys' legs is told to lie with his head in a very uncomfortable position under the table until he is cured."

OBSERVATIONS ON THE PATHOLOGY AND TREATMENT OF CHOLERA. By JOHN MURRAY, M.D., Inspector-General of Hospitals, late of Bengal. 12mo, pp. 58. New York, G. P. Putnam's Sons, 1874.

Cholera has certainly been written about. Indeed, if our memory be not at fault, at least one monograph upon it has been published during the century. Nevertheless, as the offering of an eminent physician, who for forty years has fought the disease in its native jungles, we welcome this brochure heartily to our book-table. It contains but little that is absolutely new, but may be read with profit by almost any one, and may be accepted as an excellent guide in the treatment of this affection. One point made by the author is worthy of close attention. It is the existence of a stage of malaise before the premonitory diarrhœa, and the belief that the attack may often be aborted by judicious treatment during this period of incubation. The proper treatment of this premonitory state, Dr. Murray believes, is to be found in sustaining the strength, promoting digestion, keeping up the spirits, and avoiding exhaustion,—the free use of alcoholic stimulants and purgative medicines. The use of spices and quinine are advised, the latter very strongly so, in doses of two grains three times a day. Change of air and location, *i.e.*, removal from the infected district, is often of service, especially in the cases of encamped troops.

A CONSPECTUS OF THE MEDICAL SCIENCES. By HENRY HARTSHORNE, M.D. Second Edition. H. C. Lea, Philadelphia, 1874.

This work sums up medical knowledge in a thousand pages as an aid to student-cramming. So long as there is a demand for books of this kind, some one will supply it, and of its kind this book is about the best we know. It would, however, be a most hopeful sign of a medical millennium if such books ceased to pay.

GLEANINGS FROM OUR EXCHANGES.

TREATMENT OF FIBROUS TUMORS OF THE UTERUS BY HYPODERMIC INJECTION OF ERGOTIN (*The Chicago Medical Journal*, June, 1874).—Dr. A. Reeves Jackson and others report seven cases of uterine fibroid tumors, in four of which there was diminution of the size of the tumor, with marked general improvement; in another the tumor was not affected, but the pain and hemorrhage were destroyed; in one the tumor disappeared entirely and permanently, and in one there was no improvement whatever. The solutions of ergotin all produced pain, and were occasionally followed by abscesses: it was, therefore, found advisable to prepare a solution as follows: "Fifty grains of the extract (Squibb's) are dissolved in two hundred and fifty minims of water, the solution filtered, and made up to three hundred minims by passing water through the filter to wash it and the residue upon it. It represents ergot grain for minim, free from alcohol or other irritating substance." This rarely produces any pain or inflammation.

THE DIETETIC TREATMENT OF DISEASE (*The Lancet*, May 23 and 30, 1874).—Dr. E. A. Parkes found, in the course of some experiments on healthy men with different kinds of food, that a diet of dried meat and bread, without fats or vegetables, produced in two or three days very great indigestion and depression of spirits, with an acneiform eruption on the face and shoulders. These symptoms were at once removed by adding starches and butter to the same diet. This observation seems important in connection with dieting in fevers, where often such quantities of animal broths are given, and, with the exception perhaps of a little arrowroot, no starches and no fats are ordered. It might be that the best treatment for "irritable gastric dyspepsia" would be not to give vegetables at all or any nitrogenous food, but for two or three days to let only starches and fats, in some digestible form and without salt, enter the stomach. A meat diet has in some cases seemed to have a special influence on the skin,—psoriasis inveterata and eczema squamosum having been cured by Bantingism, omitting the alcohol used in that system. A purely non-nitrogenous diet lessens in a very great degree the acidity of the urine, and does so by preventing the formation of the acid. It also markedly reduces the power of the heart within twenty-four hours after the commencement of the diet. The beat is more feeble, the pulse is smaller and softer, and, if the sphygmograph is used, the height of the up-stroke is only half of what it is in the normal state of the man. This action may be useful when we wish to subdue a powerfully-acting and excited heart, or in the treatment of aneurisms. The men experimented upon took, on an average, ten ounces of arrowroot, six ounces of sugar, and two and one-third ounces of butter in each twenty-four hours. This quite satisfied hunger, and maintained weight and health. If it be deemed necessary to add nitrogen without giving meat or bread, a little ground rice may be added, one ounce of which contains three and a half grains of nitrogen; or an egg may be given, one two ounces in weight yielding about nine and a third grains of nitrogen. In regard to the influence of alcohol on appetite and digestion, the evidence obtained from three healthy men as to any increase of appetite or more vigorous digestion from small doses of alcohol was found to be rather more negative than positive, anything over two fluid-ounces of alcohol being found to lessen appetite if the stomach was empty, and to injure digestion. The quantity of alcohol given for the particular purpose of increasing appetite should not exceed one fluidounce of absolute alcohol in a day, and half an ounce is often enough. It should be given with food, and for many patients the best plan is to give rectified spirit, properly disguised, as a medicine. If a fattening effect is desired, and no gouty tendencies exist, beer containing a good deal of malt extract is suitable; if salines and acids seem desirable for the kidneys, the light French wines are appropriate; but in any case a natural wine as little doctored as possible should be insured.

THE RELATION BETWEEN ARTERIAL TENSION AND ALBUMINURIA (*The British Medical Journal*, May 9, 1874).—Dr. George Johnson objects to some recent assertions as to the cause of albuminuria in certain cases of scarlatina. Clinical observations have shown that in such cases there is often a condition of high arterial tension before the occurrence of albuminuria, and it may be assumed that this is the result of contraction of the terminal muscular arterioles excited by a morbid condition of blood; but it is not evident how this arterial tension explains the albuminuria: on the contrary, undue contraction of the renal arterioles excited by morbid blood would tend to lessen capillary engorgement in direct proportion to the increase of

arterial tension to which it gives rise. It is intelligible that albuminuria may result from engorgement of the Malpighian capillaries consequent on an impeded return of blood through the veins, or an increased afflux through unduly relaxed arterioles; but it is difficult to understand that albuminuria can be a direct mechanical result of increased arterial resistance and tension, and still more difficult to explain in this way the desquamation of renal epithelium and the other phenomena which occur in cases of acute Bright's disease.

POISONING WITH SIX DRACHMS OF HYDRATE OF CHLORAL.—Dr. Levinstein reports the case of a man of thirty-five, who was brought to a hospital at 9 A.M., having, with suicidal intent, half an hour before, swallowed six drachms of hydrate of chloral. He lay in a profound sleep, with congested face, heavy breathing, and pulse 100. Cold applications to the head. In thirty minutes the face became livid, the veins distended, respiration intermittent; temperature 39.5° C. Electricity was used, and led to regular breathing. In another half-hour a general pallor was observed, pulse gone, lachrymation, pupils contracted; temperature 32.9°. Injection of three milligrammes of nitrate of strychnine, upon which twitches were excited in the neck, chest, and the muscles of the arms and legs. Trismus now occurred, whilst the upper extremities were in a state of tetanic stiffness. With these symptoms the heart began to act again; temperature 33.3°. In a few minutes the collapse recurred, and was combated by frictions, sinapisms to the calves, and wrapping in warm blankets; temperature 34.6°. Respiration was kept up by electricity, but the circulation seemed completely arrested. Another subcutaneous injection of two milligrammes of nitrate of strychnine. Effect was the same as before; but, as respiration stopped now and then, galvanism was repeatedly used up to five o'clock in the afternoon. The patient remained, up to six in the evening, in a perfectly anæsthetic state. At seven the pupils reacted at the presence of a strong light, and the temperature was higher.

At three in the morning the sleep could only be interrupted by a strong galvanic current; but the patient swallowed a little milk, falling immediately into a deep sleep. At seven in the morning he could be roused by loud talking, and after taking milk he slept till one in the afternoon. Milk was given again, and he slept until 5 P.M., when he awoke quite refreshed, thirty-two hours after the ingestion of the chloral. No gastric disturbance whatever occurred, and he remained well for months.—*The Lancet*.

INTESTINAL OBSTRUCTIONS (*Atlanta Medical and Surgical Journal*, June, 1874).—Dr. Robert Battey strongly urges the persistent use of distensile enemata in cases of intestinal obstruction. He protests against the injunction contained in "Flint's Practice," that "the injections are not to be pushed beyond the point at which they are borne without much suffering," and calls in question the statement that "they will very rarely succeed after the invaginated portion of intestine has become swollen by congestion, and the peritoneal surfaces in contact have become adherent." He details successful cases in which twenty and twenty-five pints of fluid were injected until it had passed through the entire length of the alimentary canal and flowed from the mouth, and believes that in every case of intestinal obstruction, either feared, suspected, or known to exist, when the duration does not raise a well-grounded apprehension of gangrene, an anodyne having been premised, "a distensile enema ought to be the first, and for the most part need be the only, power invoked for the cure."

TREATMENT OF THE ACUTE STATE OF BLENNORRAGIA WITH CANNABIS INDICA AND BENZOIC ACID.—Dr. Lamaire says (*Jour. des Connaissances Méd.*), "During seven years I have in more than sixty cases employed cannabis indica and benzoic acid, when patients have applied to me too late for the abortive method to be resorted to, when the discharge has been purulent and micturition painful, and have never failed of success when I have employed them together. The haschisch alone diminishes the intensity of the disease, but is not always sufficient. Benzoic acid has made some cures, and several half-cures, but the two in combination have never failed.

"I advise the tincture of cannabis indica to be used in doses of two grammes, and the benzoic acid in doses of one gramme in a mucilaginous mixture, in twenty-four hours,—the usual hygienic measures being followed. For two years I have also used, with great success, injections of simple water, made as often as possible (ten to fifteen times in twenty-four hours), and have always been able to commence with the balsamic and opium treatment within four days at the farthest."—*N. Y. Med. Record.*

VULPIAN ON THE NERVES TO THE IRIS.—The dilator muscle of the iris is, it is well known, under the influence of the sympathetic nerve. It has been hitherto believed that all its fibres are derived from the superior cervical ganglion of the sympathetic. Some recent observations of M. Vulpian prove that we cannot regard this ganglion as their exclusive source. Experimenting upon dogs, he has removed altogether the cervical ganglion and adjacent part of the sympathetic trunk. Ten or twelve days afterwards, the animals having been put under the influence of curara until the motor nerves to the limbs had lost all their excitability, he applied strong induced electrical currents to the skin of various parts of the body. Uniformly there resulted a slight, but distinct, reflex dilatation of the pupil on the side on which the sympathetic had been removed. Hence he concludes that some nerve-filaments must reach the radiating muscle of the iris by some other path. Whether they pass up along the vertebral artery, or whether they are derived from the cranial nerves, is a question which remains to be decided.—*London Lancet.*

THE SIZE OF APERTURE NECESSARY FOR THE TRANSMISSION OF THE PLACENTA (*The Edinburgh Medical Journal*, April, 1874).—Dr. J. Matthews Duncan has made a number of experiments to determine the above point, and concludes therefrom that the placenta can be got away without disruption through an os of two inches in diameter, or a little more, and the hand can be passed through an os of two and a half inches in diameter, or a little more. The placenta is soft and lacerable, and can exert little force in distending the os. The hand is hard and firm, and can be used to dilate with considerable force. The os uteri is, in cases of placenta prævia, very rarely rigid and undilatable. It may, therefore, be safely asserted that, in the very great majority of cases of placenta prævia, the hand may be passed into the uterus, if the placenta can be extracted from it in a satisfactory manner without disruption.

METRRORRHAGIA TREATED WITH THE GALVANIC STEM PESSARY (*The Obstetrical Journal*, May, 1874).—Dr. J. V. Ingham reports two cases of extreme metrorrhagia which were successfully treated with the galvanic pessary, after all other therapeutic means had been exhausted. He found the following features common to both cases: 1, a persistent hemorrhagic tendency, unwilling to yield to the usual local applications; 2, an apparent similarity in the cause of the hemorrhage, it being

due, so far as could be ascertained, in both cases, to some degeneration or alteration of the mucous membrane of the uterus; 3, the same results followed the use of the galvanic pessary: the hemorrhage was supplanted by a profuse leucorrhœa, with some pelvic or uterine pains; 4, the recovery seemed to be complete in both cases, one menorrhagic period happening to both several months later, but not followed in either case by a second.

POPLITEAL ANEURISM CURED BY CONSTRICTION OF THE FEMORAL ARTERY (*New York Medical Journal*, May, 1874).—Dr. N. A. Robbins reports a case of popliteal aneurism of about three months' standing, occurring in a negro, aged 30. His leg was drawn up, swollen, and œdematous, and he was delirious from the excessive pain. The femoral artery was cut down upon in Scarpa's space, exposed, and Dr. Speir's artery-constrictor was applied. The instrument was kept on about three minutes, and then removed; pressure was kept on the femoral for ten minutes, in order to favor the formation of a clot at the constricted part. The wound was closed by wire sutures. The pain seemed to cease immediately after the operation, and for the first time for weeks the patient slept soundly. In ten days the wound healed, and in three weeks he was walking about almost entirely cured.

TREATMENT OF CHOLERA BY THE HYPODERMIC INJECTION OF CHLORAL HYDRATE (*London Lancet*, May 2, 1874).—Dr. Hall, in a paper published in the *Indian Annals of Medical Science*, states that in the cold stage of cholera, instead of exhaustion of the nervous system, as is generally supposed, there is intense irritation of certain sets of nerves. He suggests that the principle which should guide us in the treatment of this condition is the endeavor to quiet the nervous system by the action of pure sedatives, and recommends the practice of hypodermic injection of sedatives in the stage of collapse. Subsequent experiments as to the physiological effects of chloral hydrate have induced Dr. Hall to make a trial of this agent in cholera, and his practice has been followed by others with satisfactory results, so far as the reports at present extend.

ACUPUNCTURE IN DROPSY (*The British Med. Jour.*, May 23, 1874).—Dr. W. Munro reports two cases of general œdema, one dependent on organic disease of the heart, the other on anæmia. In both cases all kinds of diuretics were tried without success, but finally the former case was relieved and the latter cured by the frequent puncturing of the distended skin with small sewing-needles, making twenty or thirty punctures two or three times daily. This procedure always gave immediate relief to the dyspnœa and other distressing symptoms.

APPLICATION FOR BURNS.—M. Lebigot recommends the following mixture as having been very successful:

R Cape aloes, 4 ounces;
Water, 10 ounces;
Alcohol (90°), 3 ounces.

The ingredients are to be melted together in a china plate over a slow fire, allowed to cool, and then filtered, after which three more ounces of alcohol are to be added. It is then ready for use. A tablespoonful of the mixture mixed with a teaspoonful of acetate of lead and twenty tablespoonfuls of water constitutes an excellent remedy. It is to be applied morning and evening on the burnt parts.—*London Lancet.*

FORMULA FOR TASTELESS COD-LIVER OIL.—

R Ol. morrhue, 3ij;
Spt. lavand. comp., 3i;
Spt. vini Gallici, 3i.—M.

—*Boston Medical and Surgical Journal.*

TREATMENT OF WOUNDS.—The gist of Dr. Abeille's work on the above subject consists in placing a wound in the same conditions as if it were subcutaneous: protection from the permanent action of air, from the presence of sanious and serous liquids, etc. His method is contained in the three following points: 1, immediate reunion of wounds; 2, rare dressings every three or four days,—one is often sufficient; 3, applications of cold or tepid water to the dressings. The water is not employed with the object of "refrigerating" the surface, but simply of moderating inflammation, and of giving a degree of laxity and softness to the tissues. According to Dr. Abeille, when thus used it accelerates the process of reorganization.—*London Lancet*.

ENLARGEMENT OF THE SPLEEN IN SYPHILIS (*Irish Hospital Gazette*, May 15, 1874).—Dr. A. Weil calls attention to enlargement of the spleen as a new and important symptom of early stages of syphilitic infection. He observed it while the primary induration still existed, and remarks that it disappears under anti-syphilitic treatment. He thinks this symptom of the general blood-affection in the early period differs from the local changes which are observed to occur in the organ in the later stages of secondary or hereditary disease.

MISCELLANY.

LAUGHTER AS A MEDICINE.—*To the Editor of the Medical Press and Circular:* SIR,—Observing a paragraph under the above heading quoted from an American journal, I am reminded of a like case, forty years ago, in which I was myself the moribund patient. Many years ago, at Clifton, from excessive and forced study, I was seized with a nervous or low fever; I was confined to bed; my head was filled with thoughts and fancies of a confused and wandering kind—though reason never, I think, left me—for several nights. I could not sleep, and thought the power of coaxing that balmy restorer of "tired nature" seemed utterly gone, and all opiates made matters worse. A curious red half-circle showed itself on the whites of both eyes. I was attended then by Mr. Thomas Green (1833), of 9, Queen Square, a decidedly clever man. One day he visited me when in this wretched state of mind, and instead of doctoring me with doses he began to tell my mother, then in the room, a string of most humorous and wittily-pointed stories with great cheerfulness and brightness. It was agony to me to listen to such playful trifling in my awful state of mind. "As vinegar upon nitre, so is he that singeth songs to an heavy heart." Solomon's words I realized, till I cried out, "Oh, mother, do tell him to stop!" But on with his fun went this unsparing doctor till his time was up. No sooner had he left the room, and my mother gone down with him for a private talk about the wretched patient, than the full force of the fun and wit to which I had been compelled to listen with so much pain came on me like a flood. Against myself I began to laugh, and went on till the bed shook and my frame worked with the outburst of long-suppressed hilarity; relieving tears watered my wan cheeks, and a beautiful moisture came over the skin, and, best of all, sleep, with all arrears, resumed its blessed dominion.

IS HYDROPHOBIA MORE FREQUENT IN SUMMER THAN IN WINTER?—George W. Johnston, editor of *The Animal Kingdom*, says, "The report of the French government in 1852 was more exhaustive and minute in detail than any that had preceded it, and it has since been recognized as the most exact of all investigations concerning the pathology of the disease. Among a population of over thirty-two millions, the most careful attention was paid to every symptom having the remotest analogy to hydrophobia, with the following results: They reported 105 cases attributed to the bite of a dog, 20 to the bite of a wolf, 8 to that of a cat, and 5 to the bite of unknown animals. In 100 cases they learned when the bite was received, viz., 25 in March, April, and May, 35 during June, July, and August, 13 during September, October, and November, and 27 during December, January, and February. Statistics taken in our own country have given similar results, except that the number of cases occurring with us are shown to be greater in winter than in summer."

OVER-TRAINING.—The result of the over-teaching of children in the public schools of Massachusetts is declared to be most serious, more than two-fifths dying before they reach twelve years of age. The mortality from diseases of the brain and the nervous system is 11 per cent., whereas in Nova Scotia, where no child is, it is stated, sent to school before it is seven years old, and then only for six hours a day, the mortality from these causes is only 8 per cent. The only remark we have to make on this is, that even six hours is somewhat too much for a child of seven years old. Four hours of varied work demanding attention would, we think, be ample for any child, and the mortality might then drop to 2 or 3 per cent.—*London Lancet*.

MEANS OF DISCOVERING WHETHER RED WINES ARE ARTIFICIALLY COLORED OR NOT.—M. de Cherville, in *Le Temps*, gives the following useful hints for deciding whether red wines are or are not artificially colored: "Pour into a glass a small quantity of the liquid which you wish to test, and dissolve a bit of potash in it. If no sediment forms, and if the wine assumes a greenish hue, it has not been artificially colored; if a violet sediment forms, the wine has been colored with elder or mulberries; if the sediment is red, it has been colored with beet-root or Pernambuco wood; if violet-red, with logwood; if yellow, with 'phytolac' berries; if violet-blue, with privet berries; and if pale violet, with sunflower."

ACCORDING to a correspondent of the *Boston Medical and Surgical Journal*, a medical student can live in Vienna very comfortably for \$800 a year. A free passage across the Atlantic on sailing-vessels can often, if not generally, be obtained in our seaport towns, by a young medicus who is willing and qualified to act as the ship's surgeon.

HIPPOPHAGY.—During the first three months of 1874, 2111 horses, asses, and mules were killed for food in Paris. The number in the corresponding periods of 1872 and 1870 were respectively 1275 and 989.

DR. T. C. RENNER writes to the Department of Agriculture that several years ago he collected some poke-root (*Phytolacca decandra*) for medicinal purposes, and spread it at several places about the house to dry. Soon afterward he observed that there were many cockroaches lying dead, and upon examination found that they had been partaking freely of the poke-root. Some of the root was placed near their haunts, and the result was that it rid the premises of those insects. Since then he has communicated the remedy to others, who have tested it with satisfactory results.—*Popular Science Monthly*.

INTERNATIONAL COURTESIES.—Some time since, the *Clinic*, in discussing some actions of the *Medical Press and Circular*, used the following sentence: "The sneering allusions of this American-hating journal are easily accounted for by the well-known fact that nothing so pleases most Englishmen as derision of this country." In reply, the *Medical Press* denies emphatically that "nothing so pleases Englishmen as derision of America," and intimates that it makes more extracts from, because it finds more of interest in, American medical periodicals than from those of any other country.

THE MEDICAL PROFESSION IN AUSTRIA.—According to the latest data, the number of civil medical practitioners in Austria is 7072, of whom 3874 are doctors of medicine, and 3198 surgeons. There are 2354 military medical officers in the Austro-Hungarian monarchy, of whom 2139 belong to the army, 63 to the marine force, and 152 to the Landwehr.

DR. GEORGE DERBY died June 20, of abscess of the liver and peritonitis. He was Professor of Hygiene in Harvard Medical College, and Secretary of the Massachusetts Board of Health. In both offices he is said to have been most efficient.

FINE OF A DRUGGIST.—A Paris druggist has just been fined five hundred francs for selling, without an order from a physician, pastiles made of calomel.

HYDROPHOBIA.—According to M. Bourrel, a veterinary surgeon at Paris, *canine rabies* may be prevented by blunting the canine and incisor teeth of the animal. He has tried it.

IN Bremen, a sum of money has been collected to offer as a prize to the discoverer of the most economical and æsthetic mode of performing cremation.

PROFESSOR ROKITANSKY, of Vienna, has had the dignity of Baron conferred on him, as a Commander of the Imperial Austrian Order of Leopold.

CHOLERA attacked 765 persons in Upper Silesia during the period from February 1 to April 28, causing 388 deaths.

NOTES AND QUERIES.

THE MEDICAL STAFF, U.S. ARMY.

TO THE EDITOR OF THE PHILADELPHIA MEDICAL TIMES:

SIR,—At a time when the position of the medical staff of the army is occupying the attention of the American Medical Association and the

profession generally, I deem it advisable to bring before them one or two of the rules and regulations appertaining thereto, in order that, through their influence, orders which bring obloquy upon some of its members may be remedied; or, at any rate, if this be impossible, to show the present position of the medical staff. Instead of becoming more independent, as it should, in order to secure efficiency and fearless action on the part of medical officers, it is growing more subservient and powerless, even in its own department.

About three years ago, an order was issued—not, I am convinced, with the sanction of the Surgeon-General, for we all look upon him as a gentleman of the soundest sense and judgment—to the effect that "Soldiers must be examined by their captain or lieutenant prior to being sent to the surgeon." To the profession at large, such an order speaks for itself. It injures the soldier, for the simple reason that a man of bad character may very possibly be sick, and dangerously sick, too, but he is not allowed by Lieut. Smith or Jones to go on the sick-list, because said Smith or Jones knows him to be a man of bad character. Such an edict causes the doctor to be regarded as a secondary individual by the sergeants of companies or by tyrannical officers,—in fact, by all at the post. I ask, then, who is the doctor—Smith, Jones, or M.D.?

If Lieut. Smith's wife is sick, does he examine her case, and neglect to call in the doctor because he is of opinion that Mrs. Smith is malingering? Has Lieut. Smith studied medicine or hygiene? Has he studied that difficult subject, "feigned diseases," that such power is to be given him, to the ignoring of regular medical officers? Probably Lieut. Smith has read very little of anything, but may be an excellent judge of cigars and sutler's bad whisky, or be competent to decide upon the merits of the billiard-table, or he may be A1 from West Point, but he is certainly not a doctor, and I assert, and am sure my corps will unanimously support me in my assertion, that said Smith is not competent to decide whether a soldier is sick or not. Such an absurd regulation exists in no other army in the world. I quote it to show that we are retrograding, and becoming more subservient to the line, since the close of the war. Many line officers who look upon it as an infringement of the rights of the medical profession ignore said order, and fortunately many such still remain in the service. How long they will continue remains to be seen, since the periodical pseudo-economical fits of Congress are constantly rendering their positions less stable.

The assignment of medical officers is on a wrong system. Medical officers should be assigned by the Surgeon-General (and not on his recommendation) to the several departments, and, in these departments, by the medical directors of such departments, according to their rank in the corps. This is not done, and what do we find? Medical officers at the head of the list of captains serving at bad or inferior posts, and junior captains at larger or good posts, and, frequently, contract-physicians at better posts than either of the former.

The rank of an officer tells in every other department; why not in the medical? This mal-assignment, if I may be allowed to use the term, frequently arises from favoritism. Dr. Ellis truly says, in his "Diary of an Army-Surgeon," "But with the same system of favoritism that has cursed the army, many were given positions totally unfit for the service, to the unjust exclusion of more competent and experienced men." As in every other branch of the service, a medical officer should, by law, be allowed to claim precedence of posts according to rank, regardless of his agreeableness, or prowess at billiards, or ability for giving dinner-parties, or the beauty of his wife. "*Palmar qui meruit ferat*."

Two steps require, then, to be taken to make the medical staff desirable: 1, the medical officer must be the doctor; 2, medical officers must be assigned strictly according to their rank.

Could the American Medical Association prevail on Congress to pass "acts" to effect these desirable objects, it would receive the lasting gratitude of the medical staff.

A MEDICAL OFFICER.

ERRATUM.—The name of the President elect of the Massachusetts Medical Society is B. E. Cotting,—not Colting, as incorrectly printed in our issue of June 20.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY, FROM JUNE 23 TO JUNE 29, 1874, INCLUSIVE.

COOPER, GEORGE S., SURGEON.—Assigned to duty as Post-Surgeon at Benicia Barracks, Cal. S. O. 60, Department of California, June 17, 1874.

DE HANNE, J. V., ASSISTANT-SURGEON.—Granted leave of absence for four months. S. O. 138, A. G. O., June 23, 1874.

SATURDAY, JULY 11, 1874.

ORIGINAL COMMUNICATIONS.

THE OPERATIVE TREATMENT OF PLEURAL EFFUSIONS.

Read before the Philadelphia County Medical Society, March 25, 1874,

BY WILLIAM PEPPER, M.D.,

Professor of Clinical Medicine in the University of Pennsylvania.

(Concluded from page 629.)

BUT a few words remain to be said in regard to the details of the operation itself. It is desirable that the skin should be anæsthetized by ether-spray or freezing with ice at the point where the puncture is to be made, and that a short incision be made through the derm, so that the puncture of the intercostal tissues may more surely be effected. Trousseau advised that the incision through the skin should not exactly correspond with the puncture of the intercostal tissues, so as to diminish the liability to the entrance of air; but this is rendered superfluous by the fact that the relations of the skin and intercostal spaces are much altered after the withdrawal of the distending fluid. The puncture must be made with a quick, fearless thrust, so as to avoid entangling the point of the trocar in the layers of false membrane which may line the pleura. The distance to which it is deemed safe to introduce the trocar may be regulated by the manner in which it is grasped in the hand.

I prefer operating with the patient in the sitting or half-sitting posture, and usually select as the point of puncture the sixth or seventh intercostal space, about in the line of the anterior border of the axilla. Of course, in the selection of this or any other spot, it is assumed that we have carefully determined that there is no adherence of the lung at the point, and that, if on the right side, there is no danger of wounding the liver. Authorities differ, however, widely in the point recommended for the puncture. Laennec recommended the fifth interspace, a little in front of the digitations of the serratus major, as being the most dependent point in the horizontal position, generally the freest from adhesions, and the seat of the greatest quantity of fluid. Walshe approves of this position, as do also Townsend and Stokes, who draw an analogical argument in favor of a high point, from the elevated position in which the discharge commonly occurs when it is spontaneous or preceded by the formation of an abscess. This latter point, however, is certainly mechanically unfavorable, and I confess myself unable to feel the force of this argument used by the distinguished writers I have mentioned. It is true, indeed, that when pyothorax discharges spontaneously externally, the point of perforation is apt to be near the mammary region, and much difference of opinion has existed as to the constancy with which this region is selected. It will appear, however, I think, that the true explanation is that the point of perforation will be determined by the

width of the intercostal spaces and the thinness or weakness of the thoracic walls. The entire surface of the thorax, in a case of extensive effusion, is subjected to hydrostatic pressure, and though in some instances there may be special determining causes, such as extreme softening of the pleura at certain spots, it seems probable that it is where the wall is weakest that this pressure gradually causes yielding and perforation. If this view be correct, it is evident that there is no special advantage in puncturing the chest so high up, except in cases of so-called "paracentesis of necessity," where the condition of the tissues warns us either that perforation of the intercostal tissues is about to take place or has actually occurred, with an escape of part of the thoracic contents into the subcutaneous cellular tissue. In such instances, no choice remains; it is preferable to perform paracentesis, and to choose a spot that will correspond with the point of spontaneous perforation. The following case illustrates this practical rule:

Case IV.—Empyema; threatened spontaneous evacuation—attempt to avert this by paracentesis; subsequent spontaneous perforation; pneumothorax; wasting purulent discharge from both openings; and death.

John G., æt. 35, a large and finely-developed man, applied for treatment at the Dispensary of the University of Pennsylvania. On examination it was found that there was a very extensive pleural effusion upon the right side, which was apparently of about eight months' duration. His general symptoms rendered it likely that it was, at least in part, purulent. An operation was proposed, but refused: internal treatment was directed, but upon his next visit there was slight redness over a spot in the fourth interspace, a little outside of the line of the right nipple. The tissues here were slightly infiltrated, and tender upon gentle pressure. Paracentesis was immediately performed, the trocar being introduced in the seventh interspace in the line of the axilla, and a large quantity of pus evacuated. The lung expanded fairly, and no pneumothorax followed. Unfortunately, ulceration of the pleura in the fourth interspace advanced, despite the relief of tension, and in a short time, when a moderate quantity of pus had reaccumulated, a spontaneous opening formed there, and discharged a small amount daily, but with the admission of air and establishment of pneumothorax. After this the case did badly; the pus became irritating in character, and the patient's position was such that, as he was unwilling to enter the hospital, it was impossible to use injections daily. The point where paracentesis had been performed also reopened; the tissues of the right thoracic walls became markedly infiltrated; the amount of purulent discharge continued quite large; cough with purulent expectoration came on, and the patient died from exhaustion. No autopsy was permitted.

Bowditch selects a point on the posterior aspect of the chest, in the eighth or even ninth interspace. A number of successful cases have been reported where the puncture was made at this part; but I confess to a feeling of insecurity in making the puncture so low down on the right side as the ninth interspace. An additional objection to this spot for the operation is, that in case it becomes necessary to insert and retain a canula, it causes great inconvenience to have it projecting on the back of the chest.

After the entire effusion, or so much of it as may be thought desirable, has been withdrawn, the canula is quickly removed, and a small pledget of lint placed on the point of puncture and fastened in place by a strip of adhesive plaster.

In cases where the effusion is found to be purulent, it has been advised by some operators not to attempt to close the opening, but immediately to introduce a bent canula, which is to be permanently retained in place. I would, however, strongly advise that after the first puncture in pyothorax the operation should be terminated just as if the effusion had been serous, since I have in several instances known a complete cure to ensue without any reaccumulation. It must be admitted, however, that such a result is the rare exception. When, therefore, it is found that the pus has again collected to a degree justifying paracentesis, it is preferable to employ a larger trocar, and at the close of the operation to introduce a silver canula of suitable size and shape, which may be permanently retained until the secretion of pus can be arrested.

Let me ask your attention for a moment to the inconveniences and dangers which have been attributed to this operation, before speaking of the indications which appear to call for its performance.

I pass over some objections which were formerly urged,—such as the danger of syncope, the danger of wounding an intercostal artery,—because, with the improvements that have been introduced in instruments and mode of procedure, these accidents are but rarely observed. A more serious objection is that paracentesis is likely to be followed by a reaccumulation of the effusion, requiring a repetition of the operation. The fallacy of this objection was long ago shown by Trousseau. It is of course evident that if the indications which positively call for the performance of the operation present themselves and paracentesis is performed before the inflammatory process has entirely expended itself, and while, therefore, there is still a tendency to further effusion, there will be some increase or return of effusion. The amount of fluid which has been withdrawn, however, will probably prevent the re-development of dangerous symptoms of over-distention of the chest; while at the same time there will be a more favorable condition for the absorption of the effusion. This objection could have force only upon the supposition that the minute puncture required would excite so much increase of pleural irritation as to lead to the effusion of serum from that cause alone. But there is no ground, experimental or clinical, for believing this.

Again, it has been objected that there is danger that a serous effusion may be replaced by a purulent one, after paracentesis. It has already been observed that the direct effects of the puncture itself are of the most trifling nature. There may be some little localized pleurisy around the puncture, but this never extends to a degree capable of causing constitutional disturbance, or of provoking purulent secretion from the pleura. If, therefore, it ever happens that a serous effusion which has been withdrawn by tapping is followed by a purulent one, it

must depend not on the mere puncture itself, but upon some accidental circumstance attending the operation. This circumstance is the admission of a large amount of air to the pleural cavity, which, in some instances, certainly appears capable of exciting an unhealthy inflammation of the serous membrane. The entrance of air has accordingly been advanced as another great danger incurred by this operation. It is to be observed, however, in the first place, that by the use of any of the methods I have described it is easy to exclude totally the air; and again, that it has been repeatedly shown by experiment that a single admission of air, even in large amount, to the pleural cavity does not usually excite inflammation. Although, however, the anxiety which has been felt on this score has certainly been exaggerated, it is undesirable to allow air to enter the chest during paracentesis, since it is possible that its action upon the particular stage of pleural inflammation present may lead to more serious results than would follow its admission to a healthy pleural sac.

Another objection which merits consideration is the danger of wounding the lung. Our knowledge of the physical signs caused by effusions in the pleural sac is so complete that although in certain rare combinations of conditions the signs may be puzzling and misleading, it is very seldom that any doubt can prevail in our mind as to the existence of a considerable stratum of fluid beneath any point where certain signs are observed, and of the consequent separation of the lung from the chest-wall. Under these conditions, then, there need never be any hesitation in introducing a delicate trocar, connected with an aspirator, which will instantaneously reveal the contact of the needle-point with fluid. It will still be said, however, that the diagnosis is not always certain, and that to insure the passage of the needle through the thick false membranes lining the pleura it is necessary to give a vigorous thrust,—vigorous enough to enter quite deeply into the lung should it be adherent beneath the point of puncture. I repeat that this accident can very rarely occur if a careful examination be previously made. And further, it is to be remembered that by grasping the trocar with our fingers at a certain distance from the point, we can easily regulate the depth of the puncture. But if, after all, the lung should receive a minute puncture, I am inclined to doubt if any serious results whatever would follow. The lung is compressed, almost immovable, and not in a condition to allow pneumothorax to occur from such a trifling wound of its pleura. As to the injury of the lung-tissue itself, my recent observations of the great tolerance of the pulmonary tissues of punctures by delicate needles have convinced me that the slight wound of the lung inflicted by an aspirator-needle would not do much harm.

Having thus alluded to the operation itself, and shown how free from danger it is and how easy of performance, it is of the utmost importance to determine exactly in what conditions it is called for, and what are the precise indications for its performance. This is the more important, indeed, on account of this very facility of performance and freedom from danger, since these have led some to

recommend paracentesis indiscriminately in all cases of pleural effusion, without regard to the presence of any distinct indications for its performance. This seems to me greatly to be deprecated. I am convinced that such views have a direct tendency to induce neglect of the means of internal treatment, which are of themselves sufficient to cure many cases of pleural effusion, and which should be scrupulously employed, even when paracentesis is performed. I am convinced that this operation may be performed, especially in cases of acute pleurisy, at so inopportune a moment as to be injurious rather than beneficial. It is surely necessary, when in France, where the use of paracentesis in acute pleurisy has been most urgently recommended, we see the question gravely raised and discussed whether the alleged increase in mortality of pleurisy during the past few years may not be due to the indiscriminate performance of this operation,—it is surely necessary to draw clearly the line between those cases of pleural effusion where it is positively indicated, and those where it is not necessary or desirable.

The indications for paracentesis are drawn from—

1. The quantity of the fluid.
2. The presence of urgent symptoms of embarrassment of breathing or circulation.
3. The quality of the fluid.
4. The failure of internal treatment.

1. The mere excessive quantity of a pleural effusion may become a very urgent indication, without regard to the cause or duration of the effusion. In cases where the entire pleural sac is distended,—as shown by absolute dullness extending from the base of the chest to the very apex, and by marked displacement of the diaphragm, liver, and heart,—paracentesis should be performed without delay. I should urge this despite the entire absence of threatening dyspnoea. In several instances, where excessive effusion had slowly and latently formed, I have known sudden death to occur, apparently from extreme interference with the heart's action. And, even if such an accident does not happen, experience has shown that these monstrous effusions are very slowly absorbed, with great injury to the general health, and usually with marked and permanent deformity of the thorax.

2. In other instances, the development of extreme dyspnoea, with marked interference with the action of the heart, accompanied by occasional paroxysms of alarming, almost suffocative orthopnoea, calls for the immediate performance of paracentesis. The intensity of these symptoms depends, usually, upon the rapidity of the formation of the effusion, and upon its quantity. Thus, a quart of serum effused within forty-eight hours will often give rise to more alarming interference with breathing than a collection of four times that quantity which has slowly formed. Still, it occasionally happens that rapid effusions are tolerated with remarkable ease.

But whenever the above symptoms appear in a marked degree, delay is dangerous, and the operation is imperatively called for.

3. In all cases where the effusion is known to be purulent, paracentesis should be performed

promptly. Absorption is, of course, impossible; and the chance of an opening through the chest-wall or into the lung, before the strength of the patient is far exhausted, should not be counted upon.

The determination of this question can frequently be based upon the character of the general symptoms, particularly upon the degree and persistency of hectic irritation. In any instance where such symptoms lead us to suspect the existence of a purulent pleural effusion, it is a simple matter to introduce a very delicate exploring-needle attached to an aspirator.

4. Even in cases of moderate effusion, when medical means have been faithfully tried for some weeks without inducing absorption, or even checking the tendency to increase of the effusion, it is desirable to perform paracentesis. The practical difficulty, of course, is to determine in any given case precisely when this time has arrived. Probably no definite law can be laid down; but we must base our action upon the rate of increase of the effusion, upon the influence upon the general health, upon the existence of a tuberculous predisposition, upon the degree of respiratory and circulatory embarrassment. In general terms, the time during which delay should be allowed is from three to five weeks.

I have thus attempted to sum up the chief indications for the operation, and which, whenever one or more of them is present, would seem to render its performance obligatory. It will thus be seen that I would recommend paracentesis absolutely in pyothorax, and in hydrothorax dependent upon the above indications, as in acute pleurisy, in latent pleurisy with serous effusion, in cancerous pleurisy, in tuberculous pleurisy, and in passive effusions, as in cardiac disease.

I cannot leave this part of my subject without again adverting to the fact that, although paracentesis cannot, in my opinion, be regarded as an ordinarily necessary and applicable treatment in acute pleurisy, it may be urgently called for in that condition. The dictum of Louis that simple pleurisy is never an immediate cause of death is erroneous and misleading. I have already alluded to instances of sudden death from pleuritic effusions which I have myself seen. Copland has known death to occur very nearly as suddenly as from disease of the heart; and Walshe states that he has seen a strong man, proved by dissection to be free from any other kind of disease, unexpectedly perish from syncope under the influence of unilateral effusion.

There is but little to be said with regard to the immediate effects of the operation. After the flow is established, the patient rarely complains of much pain except in cases where strong suction is used, and where the lung is unable to expand, or where violent cough occurs. Usually there is a decided sense of relief even during the operation, though the respirations and pulse are often accelerated owing to excitement. There is very generally dry, hacking cough, as the fluid escapes, evidently caused by the entrance of air into the pulmonary tissue and the effort at expansion. Occasionally the cough is

frequent, paroxysmal, and very painful. Occasionally, also, the violence of the cough and the consequent rapid unfolding of the lung-tissue cause the rupture of minute capillaries, so that there may be the expectoration of a little blood-streaked mucus. In this connection, allusion may be made to the peculiar copious sero-albuminous expectoration which sets in, in a small proportion of cases, soon after the operation.

After the operation is over, and the patient has become tranquil, there is generally a reduction both in the pulse and respiration. It has been asserted that in cases of serous effusion the temperature remains unchanged after the operation, while if the effusion be purulent the temperature falls. I have no thermometric observations of my own in cases of pyothorax, but in quite numerous cases of hydrothorax the temperature has either remained stationary or fallen slightly. Thus, in Case II., where the effusion was purely serous, the temperature was $100\frac{3}{8}^{\circ}$ C. at 8 o'clock P.M. on the evening previous to operation, and two hours after operation was $98\frac{1}{8}^{\circ}$, $99\frac{3}{8}^{\circ}$ six hours later, and $99\frac{1}{8}^{\circ}$ ten hours after operation.

Among the unusual phenomena met with in paracentesis is the escape of blood, more or less mixed with serous fluid, towards the close of the operation. Several cases are recorded where a free discharge of pure fluid blood occurred from the canula. I have seen this same occurrence during paracentesis for ascites, and in both instances the hemorrhage probably occurs from minute vessels in the serous membrane, or from false adhesions, which give way so soon as the uniform pressure exerted by the effusion is removed.

Case V.—Mr. B., æt. 30, of well-marked strumous constitution, had a grave attack of diphtheria in the winter of 1872-3, and had never enjoyed his previous health since. In March, 1874, he consulted Dr. Yarrow, who found him suffering with extreme dyspnoea, connected with large double pleural effusion. The origin and development of this had been entirely latent. His condition was alarming, from the extreme degree of exhaustion, pallor, and dyspnoea which were present. Internal treatment caused a reduction in amount of effusion on the left side, but proved of little avail in regard to the right side; and I was called to see the case in May, with a view of determining the propriety of paracentesis. After careful consultation, we decided to puncture the right thorax in the sixth intercostal space, at the line of the anterior border of the axilla. Dieulafoy's aspirator was employed, and seventy-five fluidounces of straw-colored serum were withdrawn. The closing portion of the operation was very painful; evidently in consequence of the powerful traction upon the expanding lung. There was still more effusion, but the flow was interrupted by the lung coming in contact with the canula. Immediately after the operation the patient was seized with violent paroxysmal cough, which caused so much pain as to require repeated doses of opium. There was immediate relief of respiration, with a return of respiratory murmur over a part of the area from which it had previously been absent. About six hours later, a very alarming syncopal attack occurred, from which he was only roused by repeated and large doses of stimulants. During the night copious sero-albuminous expectoration commenced, and in the course of the next twenty-four hours almost a pint was discharged. This was compared by the family to the fluid

which had been evacuated from the chest, consisting of a clear, serous fluid, in which a large muco-fibrinous coagulum formed. There seemed no real purulent element with it. This copious expectoration continued for about forty-eight hours, becoming mixed with a considerable amount of blood. After this it diminished, and the blood gradually disappeared. The patient experienced a good deal of relief for a few days, but rapidly relapsed. Extensive coarse friction-sound appeared over the left side, followed by effusion. Edema of legs appeared, and diarrhoea set in.

The *after-treatment* of cases in which paracentesis has been performed must depend entirely upon the character of the fluid. In cases of serous effusion, the same internal treatment and external applications must be continued after as before the operation, in the hope of preventing any re-accumulation of the effusion, and of promoting the absorption of the remaining portion. So, too, after the first puncture in cases of pyothorax, a slight hope may be entertained that the lung will expand and no fresh formation of pus occur. But in the great majority of cases the effusion recurs; and it is generally conceded to be useless to attempt to close the puncture made in the second operation. It appears to me preferable to introduce immediately a drainage-tube, so that the pus can be evacuated as rapidly as it forms, and thus, by preventing any extensive accumulation, the lung be aided in expanding. The forms of drainage-tubes recommended by various authors differ considerably; but that which has appeared to me most useful is a silver canula, bent so that the portion introduced within the thorax shall lie nearly parallel to the chest-wall and thus avoid the expanding lung. It is necessary that the external part of the tube should be guarded with a shield, to prevent it from slipping into the chest, as well as to enable it to be readily fastened in place by adhesive strips; and it must also be furnished with a plug or valve so that it can be closed constantly, save at certain intervals, when it is desirable to allow the pus which has accumulated to escape. When the secretion is active, this should be done daily; but when the pus is formed but slowly, and is healthy in character, it is sufficient to allow it to escape every other day.

In the following case, this mode of treatment will be seen to have been entirely successful:

Case VI.—Mr. T., æt. 42 years, of very strong constitution, was attacked on March 2, 1870, with acute pleurisy of left side. He was at first under the care of a homœopathic physician, and grew rapidly worse; and on May 16 there were still evidences of large effusion, with marked general symptoms, emaciation, hectic fever, and prostration. Dr. Galvez, under whose care he had recently placed himself, tapped him on May 16, low down on the posterior aspect of the chest, and evacuated about one pint of thick, discolored pus. The wound closed, and all the grave symptoms returned. The case now passed under care of Drs. F. G. Smith and S. D. Gross, by the latter of whom paracentesis was again performed on May 30. The puncture was made in the eighth interspace in the median line of the axilla, and seven and a half pints of laudable pus were drawn off, and a silver canula, with a valve, introduced. The subsequent treatment was conducted by Dr. Smith and myself in consultation. The contents of the left thorax were evacuated daily; the amount of pus

remaining over a pint for some time, and then gradually diminishing. No attempt was made to exclude air, so that an extensive pneumothorax was formed, the lung being retained in the upper and posterior part of the thorax. Still the discharge continued constantly laudable and unirritating. At first the patient's condition was apparently almost hopeless. There was œdema up to the waist; the pulse was frequent, feeble, and irritable; and hectic fever was marked, with sleeplessness and anorexia. He was placed on the use of beef-tea and milk-punch, Basham's iron mixture, f3ss four times a day, and elix. bismuth., strychnia, and pepsin, f3i after each meal. No injections into the pleural sac were employed; as the lung expanded, a canula was introduced, curved so as to avoid touching the pulmonary pleura, and with a valve, so that the contents of the left chest could be evacuated daily. The symptoms steadily improved, and as the discharge diminished and the lung expanded, moderate contraction of the left chest occurred. The canula was withdrawn towards the close of August, at which time vesicular murmur was distinctly audible down to the point of puncture. I have seen him since several times (the last time only a few months ago); he is in perfect health, stouter than ever before, and with scarcely a trace of contraction of the left side. There is full and soft vesicular murmur over the whole of this side.

Very frequently, as in this case, it is impossible to exclude the air and prevent the development of pneumothorax after operations for empyema; but unfortunately the constant presence of air in large quantities in contact with the inflamed pleura and the accumulated pus is not always so free from harm.

It is true that, by the use of Dieulafoy's aspirator or Bowditch's syringe, it is possible to make repeated punctures with delicate trocars as frequently as the pus accumulates, and thus prevent the entrance of air. As I have never, however, had the opportunity of treating a case of empyema in this way, I can only mention it as well worthy of trial, although I suspect it will prove to be attended with some difficulties of its own. But when, after any form of the operation, the pus secreted by the diseased pleura is found to become offensive and irritating, it is necessary to employ some means to destroy its putrescence and irritating character, and modify the action of the inflamed surface. This is best done by injecting through the canula a quantity of whatever fluid seems appropriate to the case, so that it may be brought into thorough contact with the pleural surface. The amount of fluid thus injected should usually be from four to eight fluidounces; and after it has remained in the cavity of the chest a sufficient time, the valve of the canula may be opened, and the patient's body moved so as to cause it to escape. The frequency with which these injections should be repeated must vary with the effect produced by them; the milder ones may be used daily, while the stronger solutions, used with the view of altering the character of the action of the pleural surface, may be repeated at longer intervals.

In cases where the discharge is not offensive and putrid, but yet seems to possess irritating properties, quite large injections of tepid water frequently exert a soothing influence, and relieve irritation. If the discharge has become highly offensive, a small quan-

tity of liq. sodæ chlorinatæ or of a glycerole of carbolic acid may be added to the water.

When the putrescence has been relieved, and yet an obstinate, purulent discharge is maintained, ioduretted injections, as originally recommended by Boinet (*Archives Générales*, May, 1853), are probably the most useful. They have been frequently employed, nearly always with some beneficial result, and not rarely with the effect of gradually checking the discharge and aiding in a perfect cure. In my own experience, when the strength of the injections has been judiciously apportioned, I have never known the slightest ill consequence to follow their employment.

The formula recommended by Boinet was as follows:

Tincture of iodine,	10 to 50 parts;
Iodide of potassium,	1 to 5 "
Water,	100 "

Trousseau employed an injection of medium strength, containing 25 parts of tincture of iodine, 1 of iodide of potassium, and 100 of tepid water; and I should recommend beginning with solutions even of one-half or one-third this strength, and gradually increasing up to the latter strength, but not exceeding it, since severe iodism has been known to follow the use of stronger solutions. As the discharge diminishes, and the lung expands and the chest contracts, so that the pleural cavity is reduced in size, the amount and frequency of the injections may progressively be reduced, until finally the canula may be removed.

It need scarcely be repeated that, throughout the entire course of this treatment, the most scrupulous attention must be paid to the internal treatment and to the diet and hygiene of the patient.

HYDRATE OF CHLORAL IN PUERPERAL CONVULSIONS.

BY EUGENE P. BERNARDY, M.D.

ON the morning (8 A.M.) of December 26, 1873, I was called to attend Mrs. M., æt. 18, first confinement. The messenger stated that she had been in convulsions since six o'clock that morning. On my arrival I found the patient just recovering from a convulsion, and immediately ordered potassii bromid. in half-drachm doses every fifteen minutes. The patient was a perfect blonde, stout but short-built; her hands and feet pitted readily under pressure. After a good deal of difficulty I succeeded in making a vaginal examination: the os was dilated to about the size of a silver dollar, *soft and very dilatable*. The vertex was presenting, but I was unable to recognize the position. During the examination the patient went into a most fearful convulsion, her face, lips, and tongue becoming almost black; the bromide seemed to have no effect whatever. I then determined to bleed, but, by desire of the family, waited for Dr. William H. Hooper an hour, when, finding the convulsions steadily increasing, I took about eight ounces of very dark blood, almost black; this was followed by a moderation of the convulsions, but did not arrest them. Dr. Hooper having arrived, a vaginal examination was made; the os was found in the same condition as before. It was then decided to etherize the patient, dilate the os forcibly, and deliver as quickly as possible.

Having thoroughly etherized the patient, we commenced the dilating process with our fingers, until the os had opened to about two inches in circumference. The position having been made out (left anterior position vertex), and the bag of waters ruptured, we determined to apply the forceps,—the head as yet at the superior strait. While Dr. Hooper made pressure over the uterus, to steady the head and prevent it from slipping, I readily applied the forceps (Bedford's); extraction was made to imitate nature as closely as possible. In one hour and a half the patient was delivered of a living child, without the slightest injury to herself or it.

After the birth of the child, the ether was withdrawn, when the convulsions reappeared, and followed one another in rapid succession, steadily increasing in intensity. We then decided to give hydrate of chloral in scruple doses every half-hour. At the second dose the convulsions ceased entirely. The chloral was kept up every hour. At all times the patient could be aroused, the chloral never producing a profound sleep.

The patient was up and attending to her household duties on the 20th of January of the present year.

In looking at the above treatment, it will be seen that bleeding and large doses of bromide of potassium (one-half ounce was given in divided doses) had no effect on the convulsions, while forty grains of chloral arrested the convulsions at once. This is the third case in which I have used chloral with success. For my first case, see the *Philadelphia Medical Times* of January 15, 1872. The second case occurred in the summer of 1872; forty grains of chloral had the most decided effect, arresting at once the convulsions.

When I first prescribed the hydrate of chloral, in 1871, I had not heard of its ever having been used in puerperal convulsions. It was only two years later that I found an extract in *Hays's American Journal* (April, 1873), which referred to an article in the "Transactions of the Edinburgh Obstetrical Society," sessions 1869-70-71, page 50, being a report of a case of puerperal convulsions brought on through fright, treated by Dr. Alexander Milne (Jan. 25, 1870) with grs. lx of hydrate of chloral with perfect success.

In Leishman's "System of Midwifery," the use of hydrate of chloral is mentioned, pages 649-50. On page 650 is given an extract from an article taken from the *Gazette des Hôpitaux* of February 22, 1873, where chloral was given in puerperal convulsions with success. This would make it two years from the time I reported my first case.

It seems, therefore, that I must have been the first to use hydrate of chloral in the treatment of puerperal convulsions on this continent. There is no doubt but that Dr. A. Milne was the first to use the article in Europe, but for its use in puerperal convulsions in America I think I can justly claim the priority.

In the administration of chloral, there is no case of puerperal convulsions in which it cannot be given without fear,—there is not that hesitancy which is found in other practice. Take, for instance, bleeding: we all know that puerperal convulsions may arise from various causes,—from anæmia as well as from plethora. Now, if we decide to bleed, before we do so we ask whether this condition arises from anæmia or plethora. If from anæmia, we cannot

bleed, for we will most assuredly destroy our patient. In giving the hydrate of chloral no such fine question is to be decided.

The commencing dose should not exceed one scruple. It is better to give smaller doses repeated than large doses at long intervals: the system seems to be able to take up a smaller dose more readily; the effect can also more readily be watched.

The formula I generally use is as follows:

R Chloral hydrat., ℥viij;

Syr. aurantii cort.,

Aq. menth. vir., āā fʒij.—M.

Sig.—Tablespoonful every fifteen minutes or half-hour till convulsions cease, then every hour or two, according to circumstances. The medicine must be given in an equal quantity of water.

TRANSLATIONS.

DRAINAGE OF THE PERITONEAL CAVITY.—V. Mussbaum (*Berlin. Klin. Wochenschrift*), having seen the suggestion of Marion Sims to facilitate drainage from the abdominal cavity after ovariectomy by the perforation of the cul-de-sac back of the cervix uteri and the introduction of a drainage-tube, made use of this mode of treatment in some of his cases.

Upon several occasions when the operation had been of unusual severity, he, by the use of this treatment, obtained successful results, although from his former experience with similar cases he looked for a different issue.

W. A.

HYPODERMIC USE OF EXTRACTUM SECALIS IN HERPES ZOSTER.—Sachse (*Berlin. Klin. Wochenschrift*) stated in a meeting of the Berlin Medical Society that in the treatment of a patient with herpes zoster, who applied to him on the 11th of November, he made use of a solution of the ext. secalis in glycerin, with the most favorable results. He saw the patient again on the 13th of the month, and found that the pain had ceased shortly after the injection had been made, and that there had been no fresh eruption.

W. A.

POISONING FROM VANILLA-ICE.—Dr. L. Rosenthal gives (*Berliner Klin. Wochenschrift*) an account of some cases of poisoning from vanilla-ice which came under his notice in the latter part of August of last year. The entire family were affected with symptoms simulating those of cholera, and the severity of the symptoms was proportional to the amount of the ice which had been eaten. A small dog, after having been allowed to lick the plates, was also attacked with severe purging and vomiting. During the same night, other cases of a similar character occurred, and upon inquiry it was found that the patients had all indulged in the same sort of ice-cream, and that it had been procured from the same café. So far as Dr. Rosenthal knows, this form of poisoning occurs only after indulgence in vanilla-ice, so that although lighter forms of disturbance of the intestinal tract may be attributed simply to the influence of the cold, the origin of these severe symptoms must be sought in some constituent of the flavoring-matter. So far, he has obtained only negative results from his experiments, and is not able to give any positive information upon the subject. He suggests, as a possible explanation, that the irritant properties may be contained in some portion of the fruit which is not fully ripe.

W. A.

EPITHELIOMA CONTAGIOSUM IN CHICKENS (Professor O. Bollinger: *Virchow's Archiv*).—It is well known that numerous epidemic affections occur among the various kinds of fowls which are kept for domestic use, but in most of the accounts which are given of such cases the details are so meagre, and so little attention has been paid to the pathological conditions met with, that it is almost impossible to assign to these affections their true place among diseases.

Bollinger has made some observations in this direction, and while making investigations upon anthrax he made inoculations upon pigeons and chickens, satisfying himself that this disease is but slightly, if at all, communicable to birds. In the autumn of 1872 he had several opportunities of seeing cases of genuine diphtheritis in the larynx and fauces in various poultry-yards in Zurich, and more lately he has devoted himself to the study of a peculiar disease to which birds of this class are subject, which gives rise to an eruption suggesting that of smallpox, and which is characterized by great virulence and power of contagion.

In October, 1872, an epidemic broke out in a poultry-yard containing twenty-six fowls, and in a short time all the birds were affected; many of them died, and others became so miserable that the owner was compelled to kill them.

Some of the bodies were given to Bollinger for examination, and he found the following conditions. The bodies of the birds were much wasted, the muscular tissue being very white. About the head, especially upon the eyelids and around the eyes, were numerous tubercles of the size of a pea, which were grayish-white and reddish in color, and of a tolerably dense consistence. On the surface they were partly flat and partly irregular in consequence of beginning ulceration. Similar tubercles were found near the nasal openings and at the ear. In the interior of the cavity of the mouth, upon the hard palate and other organs, were elevations of various sizes up to that of a bean, which looked like condylomata. The digestive tract and the genito-urinary organs were found to be healthy, with the exception of being anæmic to a marked degree.

Microscopic examination showed that the smaller tubercles and those in an early stage of development had their origin in a thickening of the epidermis, which gradually increased in extent, and pushed itself into the subcutaneous connective tissue, which at these points was much thickened. As the growths progressed they were found to consist entirely of epithelial cells, and the growths inside the mouth upon the mucous membrane were of a similar character, but had to some extent undergone fatty degeneration. From the manner in which the disease had made its appearance and spread among healthy fowls which were in communication with those already diseased, it was supposed to be contagious, and this was soon demonstrated to be the case by experimental investigation. Healthy birds were taken and inoculated with matter from the tubercles upon those which were diseased, and in a short time phenomena were caused which resembled in every respect those which had been already noted, and the same uniformity was found in the appearances given by the rhinoscope. As soon as the contagious nature of the disease was established, all the fowls kept in the yard in which the outbreak occurred were killed, and the quarters which they had occupied thoroughly cleansed and disinfected.

In the spring of 1873 a new lot of chickens was purchased, and put into another part of the same yard, at least one hundred paces from the spot where the previous lot had been confined. In a short time the new-comers were attacked with the same disease, and many of them also died. It must then be concluded that epithelioma contagiosum, which appears as an

enzootic affection among chickens and perhaps also among pheasants, is a very contagious disease, which manifests itself by a tubercular eruption about the head of the birds, consisting of a limited hyperplasia of the epithelium, occurring principally upon such spots as are not covered with feathers. As a rule, a similar eruption is seen upon the mucous membrane of the mouth and fauces, and also upon the conjunctiva, and upon these surfaces it readily undergoes ulceration and cheesy degeneration. Catarrhal affections of the mucous membrane of the head are also common in conjunction with the other symptoms, and there may be a purulent conjunctivitis with secondary panophthalmitis, together with inflammation of the lining membrane of the nasal cavities, which can go on to suppuration.

Bollinger endeavored to inoculate this affection upon quadrupeds, and found that it could not be done. This fact, he thinks, goes to confirm the view drawn from its pathological anatomy, that the disease in question has nothing in common with cowpox, as some of the earlier observers have asserted; and he concludes, further, that all that has been previously described as vaccinia among birds has in reality been contagious epithelioma.

W. A.

THE CAUSES OF ALKALINITY OF THE URINE AND THE AMMONIACAL CONDITION.—MM. Feltz and Ritter give, in the *Journal de l'Anat.*, No. 3, 1874, an account of experiments performed by them, principally upon dogs, with the object of ascertaining what modifications the urinary secretion undergoes in the healthy body under certain circumstances. These experiments were as follows: 1, the urine was mechanically prevented from escaping by ligature of the urethra; 2, sounds impregnated with fermenting material were repeatedly introduced into the bladder, or small quantities of fermenting fluids were injected and the urine retained mechanically for some time; 3, solutions containing urinary ferments, urea, ferments of different ammoniacal salts, or of urine in a state of fermentation, were injected into the veins.

The following conclusions, based upon the results of their researches, were arrived at by MM. F. and R.:

1. The urine, except in affections of the genito-urinary apparatus, is rarely ammoniacal. When this condition is found, it has usually resulted from impurities in the vessel in which the secretion has been received, or from admixture with more or less altered albuminoid substances.
2. The urine placed in contact with ammoniacal ferment takes on fermentative action with varying degrees of rapidity in different cases, depending, apparently, on its chemical composition.
3. The urine of healthy animals, exempt from vesical or renal lesions, does not become ammoniacal when retained a long time in the bladder by mechanical means.
4. Sounds impregnated with ferment do not render the urine of healthy animals ammoniacal, unless such sounds are allowed to remain a long time in the bladder.
5. Slight alkalinity is produced by ferment introduced into the bladder and retained there some time.
6. Uræmic accidents cannot be attributed to either retention of urea or carbonate of ammonium resulting from its decomposition; for the first of these substances is innocuous, and the second only produces convulsions in such concentrated doses as it is difficult to admit can be formed in the blood.
7. The decomposition of urea into carbonate of ammonium only takes place under the influence of ferments or of chemical agents (of the latter no account was taken). This decomposition does not appear to take place in the blood, for simultaneous injections of

urea and ferment do not provoke uræmic accidents. It is only by increasing the proportion of ferment that we produce symptoms, to be referred, however, rather to septicæmia.

8. The chloride, tartrate, and other ammoniacal salts produce effects similar from a physiological point of view to those of carbonate of ammonium, when injected into the blood in concentrated solutions. They are rapidly eliminated by the urine and saliva. The tartrate and benzoate do not undergo their usual transformation; the urine never becomes ammoniacal, nor does the breath.

9. These salts in a solution so dilute as not to dissolve the blood-globules modify, nevertheless, the properties of the latter. This fact is demonstrated by microscopic examination and by analysis. The capacity of the blood-globule for absorption of oxygen is diminished; its resistance to water and to acetic acid is, on the other hand, increased.

10. May not some uræmic accidents be attributed to simple retention in the economy of ammoniacal salts normally eliminated by the urine, without invoking the aid of a previous transformation of urea into carbonate of ammonium?

THERAPEUTIC NOTES.

INJECTIONS OF A SOLUTION OF ERGOTIN IN PROLAPSUS ANI.—Von Langenbeck, of Berlin, is said to have been very successful in his treatment of prolapsus ani with hypodermic injections of a solution of ergotin, in the proportion of ten parts to one hundred parts of distilled water.

After the bowel has been replaced and the point of the syringe inserted into the cellular tissue, two grains of ergotin are injected. This should be repeated for four weeks on every third day.—*Physician and Pharmacist.*

EXTERNAL EMPLOYMENT OF PERCHLORIDE OF IRON IN VARICOSE VEINS.—Dr. Linon uses compresses wet with a solution of perchloride of iron, formed by adding one part of the liq. ferri perchlorid. to twenty-five parts of water. The compresses are kept in position over the seats of the varices by means of a bandage smoothly and somewhat firmly applied. After these compresses have been in place for twenty-four hours the venous dilatations seem almost entirely removed. The compresses are kept applied, however, until they are entirely gone, which is usually in from eight to ten days, according to volume.

By this dressing Dr. Linon says he has succeeded little by little in dissipating enormous varices, accompanied by violent pain and the appearance of black points on the skin. That the good effect thus produced is not due to the bandaging alone, is shown by the fact that the varices do not return after the bandages are taken off. Flannel bandages, Dr. L. thinks, are preferable to those made of linen, since they are more elastic, will contain more of the liquid, and do not become stiff and incapable of absorbing.

The following ointment has been used successfully by Dr. Kennard in the treatment of incontinence of urine in paralytic cases:

R Morphine sulph.,
Veratrine, aa gr. x;
Axungia, ʒii.—M.

Rub well into the perineum three times daily.

HYPODERMIC INJECTIONS OF STIMULANTS IN ADYNAMIC CONDITIONS.—A writer in the *Progrès Médical* advises the administration of diffusible stimulants by subcutaneous injections in those conditions of extreme

prostration where the administration of medicine by the mouth is difficult or impossible, and where it is desirable to produce a rapid effect. Camphor dissolved in twice its weight of oil of sweet almonds or thirty to forty drops of sulphuric ether may be employed in this way. Generally the patient feels a sharp pain for a few moments following the injection, but absorption takes place quickly, and the adynamia is successfully combated.

PRESERVATION OF VACCINE LYMPH.—Dr. Preston spreads the lymph on a morsel of paper, by means of a camel's-hair pencil charged from the vaccine vesicle; he then allows it to dry. If the vaccine matter is to be kept a long time, the paper should be covered with a light coating of albumen. In order to make use of this prepared paper, it is only necessary to moisten it slightly with the breath, and then to apply a fragment to the abraded skin.

TREATMENT OF INTERNAL AFFECTIONS BY INJECTIONS OF LARGE QUANTITIES OF WATER INTO THE LARGE INTESTINE.—Dr. Mosler (*Berliner Klin. Wochenschrift*), after alluding to Gustave Simon's demonstration that comparatively large quantities of water can be injected into the large intestine with impunity, suggests various cases in which this method of treatment may be made available. That such injections may penetrate as far as the ileo-cæcal valve has been shown in cases in which fistulæ have existed in this neighborhood. In several such cases, water introduced into the rectum has made its appearance within a few minutes at the fistulous orifice.

The best position for a patient while receiving such injections is on the elbows and knees, occasional lateral movements favoring the penetration of the fluid. The position on the back, however, may also be used. The usual injection-syringe may be replaced with advantage by a reservoir, hung at an elevation of two feet, and connected with a rubber tube and nozzle. This arrangement insures a steady and equal pressure of the fluid, which may be controlled by compression of the tube by the finger and thumb. Even such large quantities as five to nine pints of water may be slowly introduced without inconvenience.

The cases in which this method may be employed are the following: 1. In the different forms of intestinal obstruction, particularly such as arise from accumulation of fæces. 2. In cases of internal hernia, particularly diaphragmatic and retro-peritoneal. It is understood that it is only at an early period this method may be of use. Later, when softening of the tissues has set in, it would of course be dangerous. 3. In many diseases of the large intestine, particularly dysentery, where the injection may first be of use in cleansing the intestine of irritating debris, and then may be employed to make topical applications of astringent and disinfecting liquids. 4. In different forms of icterus, particularly the catarrhal, and in obstruction of the ducts by gall-stones. Recent researches have shown that injections of water into the intestinal canal augment the secretion of bile, which, from being thick and viscid, becomes quite fluid, and tends to carry off in its course through the biliary canals the accumulated plugs of mucus, and even perhaps the calculi occupying them. 5. In certain cases when a tænia may have been dislodged from the upper intestine, but has attached itself to the walls of the colon, where the ordinary tæniacides cannot reach it. In such cases an injection of mingled tepid water and milk to the extent of several pints often serves to bring the offender away. In the case of seat-worms the efficacy of such injections is unquestionable, and they should be large, for the parasite is as often found in the entire length of the large intestine as in the rectum alone.

PHILADELPHIA MEDICAL TIMES.

A WEEKLY JOURNAL OF

MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY

J. B. LIPPINCOTT & CO.,

715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, JULY 11, 1874.

EDITORIAL.

REPORT OF THE PHILADELPHIA BOARD OF HEALTH.

IT is very rarely that a conscientious journalist has an opportunity to say a word of praise regarding any matter connected with our city government. Wendell Phillips's assertion that republicanism has never yet solved the problem how to rule large cities has too much truth in it. *Raptores et oscines*, the birds of prey and the finches, the plunderers and the plundered, the politicians and the people, express the general condition of affairs. It is therefore with unfeigned pleasure—the pleasure of a novel experience—that we commend most heartily the Report of our Board of Health. Who its real author is we do not know, but the work has apparently been mainly performed by Dr. William H. Ford, and we congratulate him and his coadjutors on the result. Of course, in the space of an editorial we cannot follow the long line of statistics, reproof, warning, and argument here marshalled, but for the sake of those who may not see the report we note a few things that have especially attracted our attention.

First in importance, it seems to be clearly made out that Philadelphia is the most healthy city in the world, so far as the records are known. This is shown by the following figures, compiled from the report of the English Registrar-General:

"According to the report referred to, then, the annual death-rate per thousand inhabitants of certain prominent cities is as follows:

Philadelphia	22.1	Turin	30.4
London	22.7	Florence	31.6
Paris	24.4	Rome	32.2
Bombay	27.6	Vienna	34.4
Berlin	29.9	Madras	37.6"
New York	30.1		

A curious fact which shows the distinctively religious cast of the community is that of 7891 marriages which occurred during the year, only 53 were civil, all the others being performed by clergymen, using religious ceremonies. Whether there is any connection between the low mortality and the decidedly religious tone of our people is, perhaps, hard to say. But factors whose influence in reducing the death-rate cannot be gainsaid are the wide extent of territory covered, the exceedingly comfortable housing of the poor, with the consequent lack of crowding, and the excellency of the food and water supplies. Although our saying it may raise a cry of horror among the orthodox sanitarians, yet we have long harbored a suspicion that the lack of sewerage and the habitual use of open cesspools that prevail have something to do with the great freedom of our city from malignant epidemics of typhoid fever and similar diseases.

A discussion of this point at length would lead us too far away from the matter immediately at hand, but we may briefly indicate a few of the reasons for our suspicions. It is, we think, well proven that decaying animal matter is not nearly so deleterious to human health as when the putrefying mass is a mixture of vegetable and animal matter; and the more complex this mixture is, the more serious are the results apt to be. Now, in sewers, animal and vegetable matters of all sorts are conjoined into one mass. In cesspools usually, at least in this city, the contents are almost wholly animal. Again, the risk to health depends more upon the concentration than even upon the amount of the poison. In open cesspools diffusion of the mephitic vapors occurs. In sewers, badly or not at all ventilated as they often are, the vapors collect into densely poisonous masses. Further, cesspools are almost universally distinct from the dwellings, whilst sewers connect, by means of the water-closets, directly with the palace as well as the hovel, and no words of ours are needed to call up examples where a sudden puff or a diffusing stream of vapor rising from the water-closet has produced most serious illness. Be these things as they may, the fact remains that malignant, epidemic, contagious typhoid is almost unknown in this city. Out of some hundreds of cases of enteric fever which have come under our notice, we have never yet been able to trace one to a definite introduction of a poison into the system, and we have never seen any

epidemic influence, and have never witnessed the slightest contagion.

The Philadelphia system of emptying the cesspools is certainly as disgusting as it is disgraceful and inexcusable. We suppose there is not one of our city readers who has not, when taking ladies home from parties, opera, etc., been compelled to pass by the practically open night-carts, with the buckets of filth passing from hand to hand, and to breathe an air perhaps as heavily laden with the curses and obscene language of the degraded workmen as it is with the vilest of odors. According to the report before us, there are several machines which obviate all this. One of them, which works upon the same principle as Dieulafoy's aspirateur, seems to us especially commendable. A metallic air-tight tank has the air pumped out of it by means of machinery whose motive power is found in the wheels of the cart which conveys the apparatus to the place where it is to be used. Then, a metallic pipe being run into the cesspool and a cock opened, all the liquid and semi-liquid contents are noiselessly and odorlessly transferred to the chamber or chambers employed. After this, the comparatively small amount of matters too solid to be pumped up may be removed by means of metallic buckets with screwed covers.

Great interest always attaches to the statistics of marriages and of births and deaths in a community. We have already noted the number of the first of these, but may now mention, as instances of the ruling passion strong in death, that two men over eighty years of age took unto themselves blooming brides,—one of the latter being in the thirties, the other in the forties. The number of successful births during the year was 17,811, of still-births 891, of deaths 15,224: so that our city added to its population some twenty-five hundred persons by natural increase.

In praising, as we have done, the report before us, it is not because we are satisfied with the sanitary administration of our government, but because the health board seems to be doing all it has power to do, and because it is continually trying to influence those great curses of Philadelphia,—its City Councils, or legislative bodies, and its executive departments.

Lying between two rivers, all bathing is prevented by a stupid application of a good ordinance, and no free bath-houses are provided for use during our intense summer heat; surrounded on all sides by suitable country, the dead continue to be actually piled one upon another in cemeteries situated in the oldest and densest portions of the city.

With a past reputation for cleanliness second only to that of Holland, and paying enormous sums yearly to contractors for cleansing our streets, the filth so abounds in our city that Dr. Ford must have meant to be facetious when he says the work of street-cleaning has been "conducted under contract;" if he had been writing soberly he certainly would have put it, "neglected under contract." So we could go on complaining *ad infinitum*; but what is the use? who cares? Surely not the "ring" that rules us with its iron despotism.

FROM a letter dated London, June 10, 1874, received by a medical gentleman of this city, we learn that Mr. Erichsen is about to visit this country on a tour of pleasure and of observation. He will leave England on the 30th of July; and, after spending a few weeks in Canada, where he has friends and connections, he will pass into the United States, where, we are sure, he will everywhere meet with a cordial welcome from his professional brethren. As a surgical author, Mr. Erichsen has won for himself a world-wide reputation.

PROCEEDINGS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

THURSDAY EVENING, MAY 14, 1874.

THE PRESIDENT, DR. WM. PEPPER, in the chair.

DR. L. A. DUHRING presented, under the microscope, a section of *lupus vulgaris*, a full description of which will appear in the next number of the *Medical Times*.

Dr. C. H. BURNETT exhibited a *polyp removed from the left ear* of a large, healthy young man, 21 years old. The patient states that he has been aware of the existence of the polyp in his ear for seventeen years. He assigns no reason for its occurrence, and says there has never been much discharge attending the growth of this body in the ear. There has never been any operation even attempted on the ear, although he has frequently requested physicians to remove the polyp since it has extruded itself from the orifice of the meatus.

Upon inspection of the affected ear, I find the orifice entirely closed by a "button" of the polyp, covered with integument, and a trace of hardened secretion around the orifice of the meatus, at the sides of the aforesaid "button." There is no odor whatever, nor has there ever been, according to the patient's statement. It was impossible to see beyond the already crowded orifice of the meatus, and I therefore, after testing the hearing, proceeded to extract the polyp.

The hearing for a watch, audible at forty feet, was reduced to contact, and the hearing for the voice was reduced so much as to render the left ear useless in conversation.

I passed the wire noose of a Blake's-Wilde's snare

over the projecting "button," and came into a widened meatus, proceeded with the instrument as far inwards as I could get it, and then constricted the innermost part of the growth, and, with the most powerful traction I could make, brought away the polyp. This operation caused the patient *no pain*. There was considerable hemorrhage for three to four minutes (about two ounces), then the hemorrhage ceased almost instantaneously of its own accord. The patient states that next day, while stooping at a spring to drink, his ear suddenly gave forth a gush of blood, but stopped bleeding as suddenly as on the previous day.

After the removal of the polyp, which was of a sigmoid shape, I found the meatus greatly widened and excavated posteriorly, where the larger curve of the sigmoid-shaped polyp had been lying.

I could not detect any odor in the ear, nor was there any confined discharge behind this large polyp.

After the operation, the hearing for the watch rose to six feet, and conversation was heard on the left side. I touched the point of attachment of this growth with chloro-acetic acid several times, causing great pain for a few moments. The pain from the use of this acid is always relieved by a syringeful of warm water. I am unable to state the appearance or condition of the membrana tympani, since the fundus of the meatus auditorius was entirely filled up by the broad cut surface of the pedicle of the polyp.

The specimen was referred to the Committee on Morbid Growths, which reported May 28, 1874, as follows:

"The large aural polyp presented at the last meeting by Dr. Burnett measures an inch in length and half an inch at its widest diameter. The growth is more or less distinctly lobulated, and covered with a firm, whitish membrane. The most pendent and exposed portion of the growth is covered with layers of flat epithelial scales, appearing as narrow, spindle-shaped cells when seen in profile. Towards the pedicle, however, the growth is covered with a cylindrical epithelium; having a long tapering extremity, and furnished with a large vesicular nucleus; the broad free extremities are still occasionally furnished with a fringed, ciliated margin. The entire peripheral border of the growth is more or less distinctly marked with low papillary elevations; in the spaces between them, corresponding depressions occur, into which the epithelial layers are seen to dip down, the size of the cells gradually decreasing and becoming more rounded until they reach the basement membrane; the whole presenting a picture closely resembling that of the rete Malpighii of the skin.

"The interior of the growth is densely packed with small, round, finely-granulated and nucleated cells; upon pencilling these away, a very delicate fibrillated stroma is seen, the fibres of which cross each other in every direction.

"The blood-vessels are quite numerous, and, being filled with a natural injection, are very prominent. The larger trunks, occupying the more central portions of the tumor, send out radiating branches towards the periphery.

"There are also present in the growth a very few mucous glands, whose efferent ducts are seen in the transverse cuts as circular spaces lined with a single layer of cylindrical epithelium. A few of the sections made, fortunately, exhibit the branching and racemose extremities of these ducts. These microscopical appearances, as briefly mentioned above, led your committee to designate this tumor as a *mucous polypus*,—by far the most frequent variety of aural polypi. The presence of the ciliated epithelium can leave little doubt as to its origin from the mucous lining of the tympanic cavity. In fact, modern investigations tend to make this mem-

brane the sole source of all aural polypi; the cutis lining the external meatus taking little or no part in their production.

"These mucous polypi of the ears do not present any histological features differing from those hyperplastic conditions of the mucous membrane of the nose, vagina, and other localities which lead to the formation of polypoid growths. Like them, they are also liable to undergo myxomatous degeneration; at least such has been the experience of some members of your committee who have given considerable attention to the investigation of aural tumors. The gelatinous consistency and translucent appearance of the lower third of this specimen led to the suspicion of myxomatous degeneration having occurred in it. But the absence of any mucin reaction and of anastomosing stellate corpuscles did not warrant such a conclusion. The only case so far recorded where the entire aural polypus was a pure myxoma is that of Steudner, to whose valuable paper* upon 'The Pathological Anatomy of the Aural Polypi' we would refer those who may be interested in the subject."

Dr. BURNETT also presented a *blue bead* seven mm. in diameter, four mm. in thickness, and perforated at its centre, removed with a mass of inspissated cerumen from the right meatus auditorius externus of a woman 68 years old.

The patient was entirely unaware of its presence in her ear, and, of course, could give no account of its mode of getting there. It was in all probability placed there in her childhood and forgotten, as it produced neither pain nor deafness.

Lately, however, the accumulation of cerumen became so great as to cause deafness, and the removal of the obstructive mass to relieve the deafness led to the discovery of the blue bead.

Dr. JAMES TYSON presented the following specimens:

1. *Lungs from a case of acute catarrhal pneumonia with secondary miliary tuberculosis of the pleura*, removed from J. W., aged 33, an Irishman and a seaman of rather intemperate habits. He had descended from healthy parents, and had himself always been well up to two months before admission to the Philadelphia Hospital on March 11, 1874. About January 1, 1874, after exposure while drinking heavily, he contracted the illness from which he died. This began with a cough, some dyspnea, and white expectoration. At first he did not think much of it; but, having lost a good deal of flesh, and beginning to have chills, flushes of heat, and sweats, he determined to enter the house. There has never been any hæmoptysis.

On admission, March 11, 1874, he was somewhat emaciated, but not very anæmic; his tongue was coated; he had no appetite, and his bowels were loose; except that he was weak he said he felt very well, coughing scarcely any, with white expectoration. There was, however, fever. He was ordered quinine, counter-irritation by a blister, and opium to control his bowels.

On *physical examination*, there was observed more motion of the left side throughout than the right. In front there was no difference in the vocal fremitus, nor in the sides of the chest. *Percussion on right side* revealed diminished resonance as far as the fifth rib anteriorly. *Left side*, resonance was normal in front and in the side.

Auscultation.—*Left lung* in front and side is normal; some harshness at the very apex. *Right lung* in front—distinct blowing breathing at apex, becoming almost normal as we reach the base; on forced inspiration, crepitant râle is heard from the third rib upwards.

Posteriorly.—*Left lung*, supplemental breathing

* Archiv. f. Ohrenheilkunde, Bd. iv. p. 199.

throughout. *Right*, from spine of scapula down, broncho-vesicular; but above, a dry crackling is heard, and prolonged, almost blowing expiration.

March 18.—Another blister to the right apex. Ordered yesterday milk-punch, his pulse being weak—114. He was ordered on admission, besides his quinine, a mixture of liq. potassæ, $\mathbb{M}\text{v}$; syr. tolu. tinct. digitalis, āā gtt. v, and liq. potassii citrat. Bowels yet somewhat loose, though easily controlled by Dover's powders given at night. Coughs very little; expectoration continues white and frothy.

March 19.—The alkaline cough-mixture was stopped, and gr. iii of quinine, j of digitalis, and $\frac{1}{4}$ of opium given four times daily.

March 22.—Bowels are regular; feels very weak. Quinine and punch continued, with a mixture of liq. ammonii acetat., ammonii carbonat., gr. v; tinct. opii, gtt. v, tinct. digitalis, gtt. vi, every two hours.

On March 21 was noted a marked disposition to drowsiness.

April 6.—Condition continues about the same; temperature ranges from 100° to $101\frac{3}{4}^{\circ}$, and pulse 120.

April 10.—Is failing; ordered a cough-mixture containing bicarbonate of sodium, muriate of ammonia, and syrup of ipecacuanha, hoping, if possible, to *thin out* the deposit in the lungs; also a large poultice over his chest.

April 16.—Is undoubtedly better since the institution of last treatment. Temperature $100\frac{3}{4}^{\circ}$, pulse 117. Skin moist. On auscultation, the crepitant râles seem to have disappeared from the right apex and the axilla. Posteriorly, however, the crepitation is distinctly heard in the right supra-spinous fossa. In the left lung anteriorly are heard coarse bubbling sounds, and posteriorly, some sibilant rhonchus. Treatment continued.

The amendment referred to was not permanent: he continued gradually to grow weaker, and died May 12, 1874.

Post-mortem examination.—On opening chest-cavity the pleuræ of both lungs were thickened: that of left to the extent of three lines; the right one less markedly so. The external surface of right pleura dotted throughout with gray granulations; pleura of left lung, which exhibited the most marked thickening, has no gray granulations; diaphragmatic pleura (right side) also covered with these granulations; and so, too, the external surface of pericardium. Old cavities in each apex, the larger one ($1\frac{1}{2}$ inches in diameter) in left apex; the smaller one, with breaking-down walls, in the right one. A solid, cheesy deposit occupying whole upper half of right lung and nearly as large a portion of the left lung. Few miliary gray granulations scattered throughout lower part of lung; but none apparently in the left. In extreme lower part of left lung, in contact with pleural base, was found a little nest of cheesy deposit, three-quarters of an inch in diameter. No miliary gray granulations in brain-membranes, peritoneum, or pericardial sac. Liver very large and fatty, weighing five pounds two ounces. Kidneys passively congested, but otherwise normal.

Remarks.—A study of the temperature-record carefully kept throughout his illness, but too lengthy to be introduced here, reveals the striking difference between the morning and evening temperature so characteristic of acute catarrhal pneumonia. Although the case was carefully watched to this end, there was no change or symptom to which we could point as indicating the onset of the miliary tuberculosis. The symptom of drowsiness was once noted as one likely to indicate this complication; but the absence of tubercle from the membrane of the brain proved this suspicion to be unfounded.

2. *Aneurism of the arch of the aorta, with enormous hypertrophy of the heart.*—The specimen was removed

from a Canadian, a baker, aged about 55 years, who had been under Dr. Tyson's observation for five or six years. He was the subject of a double rasping murmur of great loudness, which could sometimes be heard at some distance from the body. There was also a very marked upheaving impulse, which influenced the entire anterior wall of the thorax. He was subject to attacks of extreme dyspnoea, in one of which he died.

At the *post-mortem* examination there was found to be no rupture, and perhaps the most striking feature in connection with it was the small size of the aneurism, which the physical signs led one to expect to be large. This involved the extreme upper portion of the arch of the aorta, but was a true sacculum of all the coats, large enough to receive a good-sized walnut, and slightly constricted at its entrance into the vessel. The aorta was atheromatous.

The extreme size of the *heart* was also striking. It weighed thirty-five ounces, and was evidently the direct cause of the upheaving impulse so marked before death.

3. *Cancer of the gall-bladder.*—P. G., aged 63, was admitted to the Philadelphia Hospital March 5, 1874; born in Ireland; was formerly intemperate. No history of cancer in the family. Has been a very healthy man. Ten years ago an epithelioma appeared on his lip; it gradually increased in size, and has been operated upon three times,—the last time, a year ago, in this house, by Dr. Pancoast. Since admission he has presented the same pale, anæmic appearance he does now. There has been constantly aggravated dyspepsia, relieved only by milk diet; also occasional attacks of vomiting, which would last for over twenty-four hours, and accompanied by quite severe colic. His bowels are very costive, and a diarrhoea is very apt to set in when the bowels are opened artificially. The normal tympany seems to prevail throughout the abdomen. Since admission, has been taking a mixture containing tinct. ferri chlor., nitro-muriatic acid, and extract of taraxacum.

April 15.—Has been steadily improving as to his symptoms, though he still has the same anæmic, cachectic appearance. Discharged him to out-ward department.

April 28.—Has re-entered the wards, having had another attack of vomiting, with aggravated dyspeptic symptoms.

Ordered him milk diet, and a mixture containing tinct. ferri chlorid., tinct. gentian. comp., and infusion of columbo.

May 4.—There has been no vomiting for the last three or four days, but he is rapidly emaciating. Pulse 84, of fair volume. Tympanitic percussion continues throughout his abdomen, except over a small area midway between ensiform cartilage and umbilicus, and rather a little to the right of the median line. Palpation discovers an uncertain hardening above the umbilicus.

May 5.—Died this morning.

Post-mortem examination, five hours after death.—Body exceedingly emaciated, the skin being drawn tense over the bones; skin of a dark sallow color. On opening the abdominal cavity, the mesenteric glands were found very much enlarged. Pancreas healthy, as also the stomach's cardiac and pyloric extremities. Stomach was greatly distended by gas, and its upper surface, especially to the right, was firmly matted to the under surface of the liver. There was no gall-bladder found, but its place was occupied by a large cavity, which was bounded by the posterior surface of the stomach and under surface of the liver, this organ being destroyed to a considerable extent. The cavity contained some fluid, and small cheesy lumps. The wall between it and the stomach was very thin. The

intestines were healthy. The specimen was supposed to be one of cancerous disease of the gall-bladder.

Dr. J. C. WILSON presented a specimen of *aneurism of the abdominal aorta*.

J. J., æt. 24, a muscular, well-developed negro man, by occupation a waiter, was seen for the first time in the evening of April 23. He was suffering intense abdominal pain, which he stated to be paroxysmal and to have been present only six or seven days, but not severe enough to interfere with his work until the day before I saw him. The focus of this pain was in the epigastrium; it was also referred to the lumbar region and to the left chest posteriorly. It was aggravated by lying on either side, was unaffected by cough or deep inspiration; there was slight general tenderness of the abdomen. The bowels were somewhat constipated, tongue covered with a thick whitish fur. The patient had no desire for food, and no vomiting after taking it.

No thrill or marked pulsation was observed in palpating the belly. Pulse 60, rather tense. No cardiac murmur. The patient stated that he had occasionally had similar attacks, but that they had never before been so severe. The hypodermic use of morphia allayed his suffering. The next day he had less pain, and rose, having taken, at his own request, a bottle of the solution of citrate of magnesia, which purged him gently.

On the morning of April 25, after a night of great suffering, he sank suddenly and died.

The diagnosis had not been made out. After his death, it was ascertained from his friends that he had suffered for some months pain in his belly, but had never given up work on account of it. He often spoke of having strained himself in lifting, and associated the pain with that fact. He had had malaria, and had, some few years ago, venereal sores, followed by a single suppurating bubo. There was no history of constitutional syphilis. Section *cadaveris* revealed at once the cause of death. The peritoneal cavity was filled with fresh blood-clots. This blood had escaped from a longitudinal rent in the wall of a sacculated aneurism of the abdominal aorta, situated opposite the lower dorsal and upper lumbar vertebræ, and between the crura of the diaphragm. The opening in the wall of the artery was about one inch and a quarter in length, and was opposite the twelfth dorsal vertebra; the tumor itself was three inches and three-fourths long and two inches wide, and was developed anteriorly and upward, so that a portion of the right pleura was adherent to its upper extremity. Its long diameter corresponded with the course of the aorta, and its middle point was opposite the eleventh dorsal vertebra. The trunk of the cardiac artery and the superior mesenteric were given off from the sac, which in its upper part was occupied by a moderately firm clot the size of a hen's egg. The heart was hypertrophied; there was some bloody serum in both pleural cavities. The remaining viscera were blanched from loss of blood, but otherwise healthy. As the aneurism was developed anteriorly, there was no erosion of the bodies of the vertebræ. Some old inflammatory adhesions existed between the peritoneal covering of the tumor and that of the stomach. No atheromatous patches were to be seen upon the thoracic aorta; the valves of the heart were normal. There were, however, to be observed near the seat of the aneurism small, faintly-marked patches, showing slight local change in the middle coat and in the deep layers of the inner coat of the aorta, —probably commencing atheroma.

It may be not without interest to the members of the Society to state that this specimen has been kept since April 25 in a solution of hydrate of chloral, gr. xii and f3i, as recommended by Dr. Keen. The preservation is in every way most excellent as to texture, color,

and the absence of any trace of the odor of decomposition.

Dr. H. LENOX HODGE exhibited *the head and neck of the femur, removed by excision,—the head found separated from the neck by ulceration*. The patient is a delicate, pale, emaciated lad, 7 years old. About four months ago he fell, but was able to walk about that day. The next day he was obliged to remain in bed. An abscess formed, and discharged behind the great trochanter. The limb became shortened, and the inclination of the pelvis very marked. The knee is partially ankylosed, but there was a remarkable degree of motion at the hip for a case of arthritis. Excision was done at the Children's Hospital, May 6, and the head of the femur was found entirely separated from the neck, and lying in a pocket in the gluteal muscles above the great trochanter. The neck pressed against the acetabulum, and in the excision was removed as usual below the trochanters. This separation of the head by ulceration is rare, and accounts for the unusual motion at the hip prior to the operation. The case is interesting also on account of the short period in which this extensive destruction of bone appears to have resulted.

Dr. J. E. MEARS inquired of the condition of the acetabulum. He thought it a question whether the force of the injury might not have been spent upon the neck of the femur, and thus have been the exciting cause of the inflammation.

Dr. HODGE replied that the acetabulum was sound, except at the lower part of the rim. He had no doubt but that the inflammation set in on account of the injury. The physician who first examined the case treated it throughout as a fracture.

Dr. JOHN ASHHURST, Jr., said that this case appeared to have been one of the variety which systematic writers called *femoral coxalgia*,—i.e., a case in which the disease originated in the extremity of the femur rather than in either the synovial membrane or the acetabulum. It was, he believed, in such cases that separation of the femoral head was most apt to occur, the destructive process affecting chiefly the neck of the bone, which was unprotected by cartilage; whereas in the form of hip-disease known as *articular coxalgia* the head of the femur might be almost completely disintegrated, while the remnant yet remained firmly attached to the shaft.

Dr. WHARTON SINKLER presented a specimen of *extensive atheroma of the circle of Willis and other cerebral arteries*. The patient from whom it was removed was a man 47 years of age, single, who for some years had been employed in the post-office as letter-carrier and clerk. For twelve years he had served in the British army in India, and during the late war he was in the United States army. He had always enjoyed good health, and was temperate in the use of tobacco and liquor. He had never suffered from any constitutional malady.

There was no cardiac disease, nor were there any atheromatous changes in the radials.

About three years ago he had an attack of left hemiplegia. The paralysis was not absolutely complete, he being able to move slightly the hand and foot, and in about six months was able to return to light work. He could walk fairly well at the end of this time, could use the arm to some extent, and there was no contraction of the flexors on the paralyzed side.

For several months he continued to improve. Once, however, he had an attack of vertigo, which was followed by an increase of weakness for a few days.

Rather more than a year after the first attack he had a second. He did not become unconscious, but he was extremely difficult to rouse. The face was flushed, the breathing stertorous, and the speech thick. He

complained of intense pain in the head. The loss of power was on the right side, but it was not so complete as it had been on the left side in the previous attack. There was no facial palsy. It was two or three months before the patient was able to walk even a few steps. The muscular power of the limbs seemed to have returned, but the difficulty was in co-ordination. The power of locomotion in time returned to some extent, but he was never able to walk any distance, even with assistance. His gait was uncertain, and if his attention was called to anything while he was walking he was apt to fall. In fact, there was a sort of choreic condition of the limbs which was induced when voluntary effort was made, and unless he carefully observed his movements he tottered or fell.

During the next few months he had several attacks of vertigo, followed by severe pain in the head, loss of appetite, and obstinate constipation. After these attacks there was always increased difficulty in walking. For several months before death the expulsive power of the bladder became weakened, and urination was often delayed many hours.

On May 7, 1874, while sitting on the commode and endeavoring to urinate, he suddenly fell forward unconscious. He was caught, however, before striking the floor. There were no convulsive movements, but the body became rigid and the eyes were rolled up. Consciousness returned in a few minutes, but on recovering he felt as if he were choking. He could not swallow, and respiration was labored. Speech was thick and almost inarticulate. For a few days before this he had been unusually heavy and inclined to sleep most of the time. In a few hours he was able to take into the stomach some liquids; but the next day the inability to swallow returned, and the respirations became more frequent and difficult. The bladder was emptied by the catheter, and the urine examined and found to be free from albumen.

His condition from this time grew steadily worse. The surface became congested from insufficient aeration of the blood, everything that was attempted to be swallowed was regurgitated through the nose and mouth, and the patient died on May 12.

There was no increase of paralysis in the extremities, and consciousness remained almost to the last.

Post mortem forty-eight hours after death. The body was in a good state of preservation, having been kept in ice. The veins of the scalp were full. The skull was brittle, a corner breaking off when the calvarium accidentally dropped on the floor. Dura mater not unusually congested. In the superior longitudinal sinus was a firm white clot extending almost its entire length. The arachnoid was opaque over its convexity, but was more especially so at the base. A white clot occupied the right internal carotid. The vessels of the circle of Willis were enlarged and extensively atheromatous. The right middle cerebral artery was almost double the normal size, and stiffened with atheromatous changes; the left was in very much the same condition, and in the under surface of the middle lobe, where the vessel rested, was a spot of softening the size of a pigeon's egg. On section of the brain, the puncta vasculosa were prominent and some serum exuded. There was a moderate amount of fluid in the ventricles. In the left corpus striatum was a patch of softening as large as a filbert. No change in the right. In the right crus cerebri was a small spot of softening, which presented a dark color with many almost black points. A fragment of this was kindly examined by Dr. Tyson, who found only pigmented cells and no hæmatoidin crystals. There were adhesions and recent lymph in the right pleura, and the base of the right lung was somewhat congested. The liver and kidneys were gorged with blood, but otherwise healthy.

MEDICAL SOCIETY OF THE COUNTY OF ALBANY, NEW YORK.

SEMI-MONTHLY MEETING, APRIL 8, 1874.

DR. WM. H. CRAIG, President *pro tem.*, in the chair.

DR. CHARLES DEVOL reported the following case of *abscess within the cranium, resulting from inflammation of the inner ear*:

R. H., æt. 34, Scotchman, mechanic, had been subject to frequent attacks of violent pain in the right ear for several years past. Ten days prior to death he had a severe attack, which demanded active treatment for its relief. The patient had violent chills, which came on at irregular intervals, followed by coma, for four days before death.

Excepting these attacks, he was seemingly healthy.

Autopsy, 24 hours after death. Rigor mortis marked. Body rather emaciated.

Encephalon.—Left hemisphere congested throughout; lateral ventricles distended with clear serum. The surface of the right hemisphere was covered with thick greenish-yellow pus, in quantities sufficient to compress it considerably. The base of the brain was not involved, nor did the inflammation extend much into the sulci. Gray matter on section of a greenish-brown tinge.

On the right side, between the dura mater and petrous portion of the temporal bone, was a small quantity of pus, limited to a space two inches in diameter. The dura mater was discolored, but not perforated. This communicated with the internal ear, which was filled with pus. The tympanum was destroyed.

Thorax.—Lungs normal, excepting hypostatic congestion. Old adhesions of pleural surface throughout the right side, extending to the diaphragm. Heart healthy. Pericardium contained three fluidounces of clear serum.

Abdomen.—Kidneys showed recent congestion, very marked; the blood oozing profusely on section, and the tissue of a dark-red color, otherwise healthy; spleen normal; liver somewhat enlarged, with rounded edges.

The other organs were in a normal state.

DR. DEVOL said that, if possible, a careful diagnosis should be made in diseases of the internal ear: cases with acute local pain, with delirium and chilliness, indicate participation of intracranial tissues in the disease. He recommended a careful examination of the meatus auditorius. If pus escaped, it might be from the internal ear. The bones may be carious, and the semicircular canal may be destroyed; and ulceration, inflammation, and suppuration may exist in the cranium, involving dura mater or brain, or both.

DR. VANDERVEER presented the pathological specimen of Dr. Devol's case, and exhibited that portion of the dura mater diseased by contact with pus. This disease of the ear was supposed to have existed for four years. There was entire destruction of the small bones of the ear, also of the semicircular canal. The mastoid cells were implicated.

DR. J. B. STONEHOUSE asked the experience of the Society,—whether they had noticed a preference for abscesses following otorrhœa on the right side of the cranium.

DR. E. H. DAVIS narrated the following cases:

He was consulted by a farmer, who complained of having taken cold in his left ear. There were earache, and tenderness, and swelling, with obstructed hearing. He prescribed remedies calculated to relieve, and did not hear from his patient for three or four weeks, when he was called to see him. The patient could not hear, and suffered much from pain back of the ear, which continued until suppuration took place and discharged freely. A portion of the temporal bone became detached

from the surrounding bones some weeks after. He lived for about four months after this; his appetite remained good, and he was comfortable a part of the time. The loose bone never exfoliated; the patient became comatose, and died. The disease was on the left side.

Another very similar case had since occurred in his practice, of inflammation and suppuration of the left ear preceded by moderate earache; the integuments inflamed; abscess formed, which, being incised, discharged freely; and large pieces of bone were exfoliated during the next two years, when he finally recovered, and his hearing was restored.

Dr. CHARLES DEVOL inquired how great a destruction of surface in case of burns was necessary to prove fatal.

Dr. JAMES S. BAILEY said that he had met with a great number of cases of burns in the Southern States, where it was not uncommon in clearing land, in burning brush, for negro women's dresses to take fire, and, before they could be extinguished, for them to be burned severely. He had also seen several fatal cases since living in Albany. According to his experience, in cases where one-eighth of the surface was burned, especially if upon the abdomen and chest, death had ensued. He detailed the case of a child who had died in twenty-four hours from shock; also a case of an adult, who had survived the shock, and seemingly had a good prospect for recovery, but died between the third and fourth month, from exhaustion. When asked the course of treatment pursued, he said he stimulated until reaction had taken place; then supported, and used externally carbolic acid, with glycerin and water.

Dr. DEVOL said that his patients, after being severely burned, had complained of feeling intensely cold, and asked the reason for this.

Dr. VANDERVEER attributed this to nervous shock. He then referred to the shock from surgical operations. He spoke of a case of amputation of the arm, when, in the absence of anæsthetics, he had operated, and the patient afterwards spoke of only the intense pain in cutting through the skin. When the large nerve-trunks were separated with the knife, it only caused a sudden nervous shock. He had used very successfully, as a local dressing for burns, a mixture of equal parts of lime-water and olive oil, with four drops of carbolic acid to the ounce, and had, in the latter stages, resorted to skin-grafting where large surfaces of the cuticle had been destroyed.

Dr. BALCH related a case, as coming under his observation during his service in the New York Hospital, of a man who fell in a vat, scalding both lower limbs below the knees. As an external dressing he had used Carron oil, pencilling the edges with a solution of nitrate of silver, and washing the limb occasionally with tepid water.

He had treated a similar accident during his service in the Brooklyn Hospital in the same manner; both recovered.

Dr. CURTIS said that he had seen the Lister's bandage used in a very extensive burn of the lower extremity, in the General Hospital at Vienna. This consisted of a paste containing carbolic acid, which was spread on tinfoil and the surface kept constantly covered with it. The large wound granulated evenly under this; the surface being painted once in two or three days with a rather weak solution of nitrate of silver.

In the case of a ballet-dancer whose body was so extensively burned that no hope of recovery was entertained, great relief was afforded by immersion of the body entirely under water,—the appliances for which are very perfect in Hebra's wards. This is the general treatment there in such cases.

Dr. DEVOL was well pleased with a mixture of glycerin, yolk of egg, and butter of cacao, equal parts: it was bland, and excluded the air effectually.

GLEANINGS FROM OUR EXCHANGES.

THE TREATMENT OF PHTHISIS BY THE PHOSPHATE OF LIME AND THE JUICE OF RAW MEAT (*The Lancet*, June 13, 1874).—Dr. Henry Blanc has found by extended experience that in severe cases of phthisis no remedies are more valuable than the juice of raw meat and the phosphate of lime, when they are administered in a form suitable to the patient and to the disease. The syrup of lacto-phosphate of lime is well tolerated at first, but after a while induces dyspepsia, nausea, and somnolence. The solution of chlorhydro-phosphate is not grateful to the patient, but it is well tolerated by those who overcome their dislike to the rough acid taste of the drug, and has given very good results. Under whatever form the phosphate of lime may be prescribed, it should *always* be taken at meals.

The meat-juice should be prepared in the following manner: A pound to a pound and a half of fresh beef, deprived of fat, bones, etc., is placed over a quick fire for a few minutes, in order to whiten and harden the external surface only; the piece of meat is then cut into two or three pieces corresponding to the size of the meat-press, and all the juice is extracted by the pressure of the powerful screw. The superficial coction is necessary to overcome the elasticity of the meat, which renders the extraction of the juice a very difficult matter unless more powerful machines be used than the simple one at present required. A pound and a half of good fresh meat gives a teacupful of juice. The juice should be prepared daily. This juice, having all the physical properties of raw meat, is easily digested, is well tolerated, and, served in the following manner, is always very grateful to the patient. The juice should be mixed with equal parts of tepid broth, made of bones, and flavored with salt and pepper, and to which tapioca, vermicelli, etc., can be added. Care, however, should be taken that the broth is never more than *tepid*, otherwise coagulation takes place, and the desired effect is not obtained.

The treatment of the consumptive patient by this method is the following: Early morning, warm milk (not boiled), with bread and butter, and, if the appetite be good, some fat bacon and eggs. At eleven or twelve o'clock, breakfast, before which a drachm of the syrup of triple phosphate should be taken; during the meal itself, a dose of the muriatic phosphate of lime, and half of the daily allowance of the raw meat juice in some broth. The meal should consist, according to appetite and digestive powers, of fish or poultry, or white meats, fresh vegetables, and a few glasses of good alcoholic wine. Dinner at six o'clock on the same principles; broth, with the remainder of the raw meat juice, and, instead of the triple phosphate, a dessert-spoonful of cod-liver oil can be taken with advantage after the meal, if the liver be not enlarged and fatty, and the digestion good. The muriatic solution, or wine of phosphate of lime, should also be taken during the dinner. At night, before retiring to rest, a cupful of warm fresh milk, diluted one-third with Vichy water.

No medicines whatsoever, beyond those mentioned, should be administered, unless some special indications or some urgent symptoms claim their use. Anodynes, narcotics, cough-mixtures, lozenges, blisters, inhalations, etc., are practically of no good, and but too often, by lessening the appetite or by irritating the patient, they increase the debility and hasten the fatal end. All hygienic rules—out-of-door exercise, abluion of the skin, etc.—should at the same time be carefully attended to. Under the influence of this treatment the appetite rapidly returns, the cough becomes less troublesome, the expectoration lessens, the night-sweats and all unfavorable symptoms decline and disappear, the patient gains flesh

and strength, and the confirmed and helpless invalid, with proper care and prudence, can enjoy life once more.

MISCELLANY.

"27th July, 1844.

"A FEW days ago Sir William Hamilton was struck with palsy, and, though he should survive, is practically gone. . . . He is an excellent, laborious, and learned man; a great sounder of intellectual depths. His learning, indeed, is vast, and was hourly amassing. An indistinct utterance, an awkward, bashful manner, with a look of apparent sullenness, and a taste for abstruse profundity, prevented his being practically a first-rate teacher or lecturer. The art of oral instruction seems singularly difficult. It is by no means implied in a complete command of the subject, even when this is joined to considerable power of speaking or of writing. A great lecturer, besides these, must be precise, yet not dry; lucid, but not superficial; animated, but not declamatory; and, above all other qualifications, he must be familiar with all the depths and shallows of his hearers' mind in reference to his language, and to the matter to be taught; so as to avoid the common and fatal error of pursuing his own thoughts, while they have no thoughts to pursue, and of driving or soaring, while they, if awake, are staring at him from the flat earth. No mistake is more usual than that of supposing that the power of acquiring and that of communicating knowledge is the same, and that the lecturer evincing the one must evince the other. And even knowledge is not all that a truly good lecturer has to teach. He has to teach the art of acquiring knowledge, the art of acquiring the habits and the powers of acquisition."—*Times and Gazette*, June 6, 1874.

ERBWURST.—It is stated that the Prussian government is building, at Mayence, a factory for the production of the famous military sausage. If the results are satisfactory, an establishment of the kind is to be erected for every *corps d'armée*. The works will be able to supply 55,000 men, and will contain steam flour-mills, bake-houses, slaughter-houses, etc., etc. The steam flour-mills will turn out 7000 cwt. of flour daily, and there is sufficient accommodation in the house, with its kneading-machines and continuous ovens, for manufacturing this quantity of flour into bread. The slaughter-house is large enough to slaughter and deliver, ready for manufacture into food, 170 oxen daily, or at least 1000 per week, to the prepared-food department, which, besides this, will manufacture prepared vegetables. Forage rations for the horses of an army of the size named will also be supplied by the works. The opening of the establishment is fixed for about the beginning of 1875.

It is stated that horses, dogs, etc., may be freed from the annoyance of flies by smearing them with a little

empyreumatic oil of juniper, using it especially on the ears and other more exposed portions.

PROFESSOR KUSSMAUL, of Freiburg, has been invited to succeed Professor Lebert, at Breslau, who is about to retire; but he has declined the invitation.

It is stated that the negotiations with Von Recklinghausen for Rokitsky's chair have been again broken off,—this time, it is believed, finally.

THE MILLENNIUM.—The *Scientific American* believes the time will come when ice will be made in all our large cities for a dollar a ton.

NOTES AND QUERIES.

DEATH FROM AN OVERDOSE OF HYDRATE OF CHLORAL.

TO THE EDITOR OF THE PHILADELPHIA MEDICAL TIMES:

DEAR SIR,—I enclose for you the following item, to be used if you desire:

Dr. I. J. Meals, of Mill Creek, Huntingdon County, Pennsylvania, died on the night of the 19th inst. from an overdose of chloral hydrate. He was in the habit of taking a portion of a solution he had prepared for his use at night to induce rest and sleep. Feeling badly, he took more than usual (the number of grains cannot be determined). He was so far restored that he was able to sit up and converse after about four hours of effort to restore him; but there was still a tendency to relapse into a stupor. He became suddenly worse, and died, seemingly from paralysis of the heart, within five hours.

Yours, very truly,

A. B. BRUENBAUGH.

HUNTINGDON, PENNA., June 26, 1874.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY, FROM JUNE 30 TO JULY 6, 1874, INCLUSIVE.

SIMONS, JAMES, SURGEON AND MEDICAL DIRECTOR.—Granted leave of absence for thirty days from 25th inst., on account of sickness. S. O. 100, Department of the Gulf, June 29, 1874.

FRANTZ, J. H., SURGEON.—Granted leave of absence for four months, on Surgeon's Certificate of Disability. S. O. 141, A. G. O., June 29, 1874.

BROWN, J. M., ASSISTANT-SURGEON.—To report in person to Commanding General, Military Division of the Atlantic, for assignment to duty. S. O. 144, A. G. O., July 2, 1874.

HUBBARD, V. B., ASSISTANT-SURGEON.—During temporary absence of Surgeon Simons, in addition to his other duties, to discharge those of Medical Director at these Headquarters. S. O. 100, c. s., Department of the Gulf.

KINSMAN, J. H., ASSISTANT-SURGEON.—Assigned to temporary duty at Fort Abercrombie, Dakota Territory. S. O. 136, Department of Dakota, June 29, 1874.

DE WITT, C., ASSISTANT-SURGEON.—Assigned to duty at Fort Macon, North Carolina. S. O. 103, c. s., Department of the South.

LAUDERDALE, J. V., ASSISTANT-SURGEON.—To report in person to Commanding General, Department of the Missouri, for assignment to duty. S. O. 144, c. s., A. G. O.

LORING, L. Y., ASSISTANT-SURGEON.—To report in person to Commanding General, Department of Arizona, for assignment to duty. S. O. 144, c. s., A. G. O.

WEISEL, D., ASSISTANT-SURGEON.—Granted leave of absence for twenty days. S. O. 103, Department of the South, June 29, 1874.

DICKSON, J. M., ASSISTANT-SURGEON.—Granted leave of absence for two months, with permission to apply for an extension of two months. S. O. 144, c. s., A. G. O.

HARVEY, P. F., ASSISTANT-SURGEON.—To report in person to Commanding General, Military Division of the Atlantic, for assignment to duty. S. O. 144, c. s., A. G. O.

SATURDAY, JULY 18, 1874.

ORIGINAL COMMUNICATIONS.

ANALYSIS OF ONE HUNDRED AND TWENTY-FIVE CONSECUTIVE CASES OF LABOR AT FULL TERM.

BY H. G. LANDIS, A.M., M.D.,

Niles, Ohio.

ONE of the first reflections which have occurred to me after a careful study of these cases is, that it is somewhat difficult to define exactly the term "normal labor." If any interference on the part of the accoucheur causes labor to lose its natural character, there should be a reduction in the number of labors usually reported as entirely natural. Thus, there seem to me to be two modes of interference of frequent applicability: prompt rupture of the membranes after complete dilatation of the os, without waiting for its spontaneous occurrence; and retraction of the anterior lip of the os even when not oedematous; neither of which is compatible with the accepted meaning of natural labor. I am firmly persuaded that attention to these two points often materially shortens the second stage even when the natural efforts are perfectly competent to accomplish the same ends, but in a somewhat longer time. There are other manœuvres of apparently little moment which can be frequently used to advantage: *e.g.*, when the foetal head is found to be imperfectly flexed during the last third of the first stage, and not making uniform pressure on the os, a little manipulation may change in a few moments what a half-dozen pains might have been otherwise required to accomplish. The time gained by such a trifling interference is no small object. Thus, assuming the case just stated, we may take at least a half-minute for the duration of each pain, interval between each pain five minutes, making a total of twenty-eight minutes. And yet this could not be called a normal labor if we accept, for instance, Meadow's definition. We should, perhaps, classify obstetrical operations, like surgical ones, into minor and capital. The intentional rupture of the membranes is as much of an operation often as opening an abscess or even tapping a hydrocele. To be brief, I have arranged these cases in three tables. Table I. contains forty-four cases in which labor progressed and terminated by the natural efforts without any interference, and presents the following data: 1, the number of the case in consecutive order; 2, the woman's age; 3, the number of her pregnancies (P meaning primipara); 4, the duration of the first, second, and third stages respectively; 5, the sex of the child; 6, its weight; 7, the presentation and position. Baudelocque's third and sixth positions seem to have fallen into deserved disrepute. Leishman's nomenclature is therefore substituted, in which the first and second positions of the vertex are the same as Baudelocque's, but the third and fourth correspond to

the fourth and fifth of the same author. Table II. presents the same data in sixty-seven cases in which labor terminated by the natural efforts, but in which there was more or less interference, sometimes demanded by inertia or some trifling complication, and sometimes made in an entirely natural labor. Table III. gives the same data in fourteen cases in which there was capital interference, and presents, also, the nature and cause for the artificial termination. The whole number may be summed up as follows: Twin cases 2; single births 123; presentations 127—*viz.*, breech 1, shoulder 1, vertex 125, of which 97 were in the first position, 22 in the second, 5 in the third, and 1 in the fourth. Of the children, sixty were males, and sixty-seven females, of which four males and one female were still-born. Of the mothers, ninety were multipara and thirty-five primipara. Their nativity was—American 43, Irish 40, Welsh 27, English 11, Scotch 2, German 1, Swede 1.

REMARKS.

One mode of interference to which I have alluded is not strictly orthodox, and needs explanation. When a labor has advanced so far that the posterior lip of the os has retreated, so to speak, beyond reach, the os may be said to be fully dilated. At the same time we will generally find the anterior lip of some length, and applied over the child's occiput, the head being normally engaged at the superior strait. So far as it does anything it certainly forms an obstacle to the descent of the occiput, if not to complete flexion of the head. If the membranes be now ruptured, the head will begin to descend with the same or succeeding pain: when it does not, I have been led to attribute the delay to the anterior lip, and have acted accordingly,—*viz.*, by placing two fingers under the edge of the lip, and endeavoring to slip or push it over the occiput. This procedure has frequently seemed to have been of great service, is very often feasible, and, when judiciously employed, harmless. I have twice resorted to Kristeller's plan of external pressure for inertia (Table II., Cases 99 and 114). In the latter case quinine and opium had each been used without effect; three pains assisted by pressure brought the head to the perineum, and delivery was then terminated without further assistance. External rotation was performed in Case 87, Table II. After complete dilatation, three poor pains brought the head nearly to the perineum. Although the pains improved in strength and frequency, there was no further advance for one hour and twenty minutes. *Diagnosis.*—Shoulders placed antero-posteriorly at the brim. With the next pain I rotated the shoulders by external manipulation; the head at once descended on the perineum, and was delivered by the succeeding pain. There were six cases of occipito-posterior positions. In three the occiput was born posteriorly: in two of these the pelvis was sufficiently roomy to allow of the easy passage of the head without anterior rotation; in the third the disproportion was too great to allow of this rotation by any means. In the other three cases there was

anterior rotation, and the occiput was brought under the pubes, twice spontaneously, and in one (Case 89) the head rotated in the blades of the forceps. At another time I hope to be able to present a careful study of this remarkable process of rotation while in the grasp of the forceps.

But one case in the series was followed by death (Table III., Case 7). An irregular practitioner had attended the woman, and repeatedly endeavored to apply instruments. I was called in consultation, and delivered the child, but, not feeling willing to be held responsible for the result of his previous manipulation, relinquished the case, which subsequently died of pelvic cellulitis and peritonitis. There were but two cases of hemorrhage, both post-partum and dependent on malarial poisoning; and in one of these ergot was given for the only time in the series. These three cases are the only ones in which recovery was not prompt and satisfactory.

Averages are deceitful, except from large figures. Nevertheless, so-called "meddlesome midwifery" can extract some comfort from these statistics. The average duration of the second stage in Table I. was 51.25 min.; in Table II., 55.34 min.; a difference of only 4.09 minutes. In many cases interference was postponed until a considerable lapse of time had suggested its necessity. Inertia, the great lengthener of labor, was present in a majority; there was an excess of 13 per cent. in the number of primiparæ, so that the aid attempted to be offered must have been of some avail. The still-births (all in Table III.) demand some explanation. No. 21 was originally attended by a midwife, who neglected to tie the cord after the first birth. There being but one placenta, or rather two intimately joined, the second bled to death before medical aid was summoned. Nos. 26 and 86 presented the alternative of craniotomy or such forcible compression by the forceps as inevitably to destroy life. No. 48 is the only case in which there could be any doubt as to the necessity of the amount of pressure employed. No. 67 is sufficiently interesting to be given in detail. Labor began July 7, in the evening. Dr. L. A. Bard was summoned, and found the os fully dilated after only two hours of labor. The pains had ceased, and were not renewed until the next evening. By 12 P.M. the head had descended into the excavation, when convulsions set in. Dr. B. at once bled her freely, which stopped the convulsions, and sent for me. I arrived at 1 A.M., and did not anticipate any difficulty after an examination. While warming the forceps the convulsions reappeared, and ether was at once administered and the forceps applied. Vigorous traction for half an hour was required before the head was delivered; after which the neck was found to be stretched, and the shoulders "stuck" at the brim, antero-posteriorly. With considerable exertion we managed to hook down the right or posterior shoulder, and finally to extract the child. There was no return of the convulsions, and she made a good recovery. I have since arrived at the conclusion that the arrest of the head just above the inferior strait after an easy descent so far, and its continuance there despite good pains, is diagnostic of delay of

the shoulders above the brim. As in a case already cited, I have no doubt that external manipulation will generally suffice to rotate the shoulders into a wider pelvic diameter.

DESCRIPTION OF A SPECIMEN OF LUPUS VULGARIS.

Read before the Pathological Society of Philadelphia, May 14, 1874.

BY LOUIS A. DUHRING, M.D.,

Clinical Lecturer upon Diseases of the Skin in the University of Pennsylvania, and Physician to the Dispensary for Skin-Diseases, Philadelphia.

THE specimen which I present for examination was taken from a patient suffering with lupus vulgaris, who at the present time is under my care. He is an Irishman, 26 years of age, and has been the subject of the disease for fourteen years. An oval-shaped, superficial ulcer, the size of an almond, existed upon the back of the wrist, from the centre of which an island of tissue was seen projecting. This piece of unhealthy-looking skin, not larger than a small split-pea, and which had not been there more than a month when first seen by me, was excised with a scalpel. Examined at once with the naked eye, it was found to be soft, gelatinous, and too tender to handle. It contained very little blood, and was pale in color, as though it had been soaked in water. It was immediately placed in a one-fourth per cent. solution of chromic acid, and allowed to remain there three days, when it was transferred to strong alcohol for a few hours, and in this manner prepared for examination. The small fragment was entirely disposed of into thin sections which were variously treated with glycerin, carmine solution, oil of cloves, and oil of turpentine. A large number of the sections were studied, all of them affording similar results.

Under a low power, 60 diameters, the tissue is seen to consist of a very thin layer of hard, horn-like epidermis, remarkable for its imperfect development as well as for the extreme paucity of its cells. Immediately beneath this stratum, which may be likened to an enveloping membrane, is found the rete Malpighii, very highly organized, and unusually distinct in outline, dipping down between the papillæ of the corium. The papillary layer is next encountered, and is seen to be clearly defined against the rete. The papillæ are prominent, and unusually large. The corium itself is totally altered in structure, the connective tissue being almost completely obliterated and supplanted by a mass of fine "granular matter," invading every part of the corium. With the power of 60 diameters this structure bears a resemblance to the spores of certain fungi, particularly those of the *Trichophyton*, which refract light in such a brilliant manner.

Here and there throughout the corium are seen lumina, varying in shape and size, but without defined border, and which manifestly result from an absence or loss of the "granular matter" referred to. This condition is everywhere noticed, in the papillæ themselves as well as farther down in the corium. A few transversely cut fine hairs are observed in some of the specimens. Gland-structure is not noticed. Such are the features recognizable with a low power. With a higher power, 500 diameters, certain points appear which may be mentioned as follows. The rete cells are noticeably large and well defined in outline, possessing the rounded

nucleus and angular-formed nucleolus with more than ordinary clearness. Their borders exhibit the prickles very plainly. The rete shows a prolific and rapid growth of cells, similar to that which is seen in other speedy pathological changes which take place in the skin, as in herpes, for instance.

The "granular matter" spoken of when viewing the specimen under a low power is now seen to be made up of a multitude of small cells, which are closely packed together, either free or imbedded in a delicate mesh-work. These are of various shapes, some being rounded, others angular or polygonal, and others oval; in fact, they vary greatly as to outline. They also are different as to size; some being relatively very large, and others very small. Some are found to be similar in size to the red blood-corpuscles, while others, the vast majority, are very much smaller. They refract light in a marked degree. Their contents show various stages of change; some of them containing fine granular matter, with a few prominent black points in their centre, while others show a tendency to further disorganization and rupture. These cells, which form the bulk of the tissue, are very numerous, and appear to invade every portion of the corium, from the apices of the papillæ downwards; they are quite evenly disseminated throughout the structure, and show no tendency to aggregate or grow about a centre. At the same time, they are found in larger numbers at some points than at others,—this being accounted for, I think, by there being a more rapid and luxuriant growth at this point on account of some variation in the original connective tissue. The cells are not adherent one to the other, but appear as separate bodies, lying close to one another. The lumina referred to, represent points where disintegration and destruction of tissue, both of the original connective tissue as well as of the new formation, have taken place. About the borders of these cavities, shreds of connective tissue are seen, but they are scanty in number, imperfectly developed, and everywhere studded with the new formation cells. Although the mass of the corium appears to consist of these cells without much of a stroma, yet upon more accurate examination it is observed that a fine, delicate mesh serves as a bed for most of them, although they are often not firmly seated in it.

The case is an interesting one, from the fact of its being a very recent formation of lupus. It is a young specimen of the disease, showing the process in its early stage, and differs in this respect from the specimens usually obtained, which are apt to be of long standing, and show a somewhat different picture, particularly as regards the rete Malpighii.

The numerous cells infiltrating the corium comprise the chief interest which attaches itself to the specimen, and these seem to agree with the observations of Virchow, Auspitz, Neumann, and others. Rindfleisch, however, takes an entirely different view of the subject, considering lupus as an adenoma of the sebaceous glands, and placing it in close proximity to the epithelial growths. This latter view is so at variance with the one commonly

accepted that at present it is merely mentioned. Hebra, Virchow, and others agree in placing lupus with the neoplasms, grouping it with elephantiasis græcorum and syphilis. Virchow considers these three diseases under the head of "granulation" tumors or growths, and adds that they consist of a decaying tissue very prolific in cells, which is rich in cells just in proportion to the degree of its pronounced character; and that the greater the number of cells it contains the smaller and less highly developed they are found to be. According to the same author, the lupus mass is made up of a collection of young, very soft, granulation-like tissue, generally abounding in vessels, which hold, as a rule, small round cells, resembling at times the cells of the rete Malpighii so much as to be difficult of diagnosis. This view corresponds in part with the examination of our case; but that the lupus cells resemble the rete cells so much as to be scarcely distinguishable the one from the other, is a statement which is by no means borne out by our investigation. The line of demarcation between rete and corium was well marked and distinct, so much so as to have been worthy of note in the report. In this connection, however, the variety of lupus, as well as the stage of the disease, whether recent or old, must be taken into consideration, for these are points which it seems to me are sufficient to render different pictures in this portion of the structure. From these few remarks it will be seen that in the main our examination is corroborated by the elaborate studies of both Virchow and Auspitz upon the pathology of this disease.

TRANSLATIONS.

A NEW METHOD FOR THE ENUMERATION OF RED AND WHITE BLOOD-CORPUSCLES.—M. L. Malassez has communicated to the *Archives de Physiologie*, January, 1874, a method of counting blood-globules, together with an account of certain apparatus devised by himself for the purpose. The process has found great favor among European physiologists, and has been made use of in several recent researches. The apparatus used by M. Malassez is described minutely in the communication referred to, but we have only space to give a few particulars regarding it.

For the purpose of examination the blood is diluted with an artificial serum, composed of one vol. of a solution of gum arabic of specific gravity 1020, and three vols. of a solution of equal parts of sulphate and chloride of sodium, also of specific gravity 1020. The pipette, of a peculiar construction, called the "mixer," in which the blood and artificial serum may be mingled in any desired proportion with great accuracy, is figured and described at length by M. Malassez. For examination under the microscope a capillary tube of known volume is soldered to a glass slide, and by the aid of an eye-piece micrometer of peculiar construction, also devised by M. Malassez and described by him in the same number of the *Archives*, the number of globules to a given volume of blood is rapidly and accurately estimated. In ascertaining the proportion of red globules the blood is mixed with artificial serum in the ratio of 1 to 100 or to 200, but in the case of the white globules the ratio of blood to serum is as 1 to 50. It is in estimating the latter that M. M.'s method more espe-

cially shows greater accuracy than those formerly in use. He concludes his paper by a series of experiments on the blood in different pathological conditions, followed out by the aid of the above-mentioned apparatus and according to the process described.

A. V. H.

RHYTHMIC MOVEMENTS OF THE VENA CAVA.—At a recent séance of the Académie de Médecine (reported in *L'Abeille Méd.*, May 11, p. 180) Dr. Colin read a paper on this subject, going to show the possession of decided contractility on the part of these vessels near the point at which they open into the auricle; a contractility manifesting itself in rhythmical movements which are sustained even after destruction of the bulb (medulla oblongata?) if the circulation be kept up by artificial respiration. These pulsatory movements have a perfect systole and diastole, and are isochronous with those of the heart.

Dr. Colin's paper was criticised by M. Vulpian, who remarked that the ideas were not new, as it has long been known that a contraction of the vena cava precedes by an instant that of the auricle. M. Bouilland drew attention to a paper by himself, read about a year ago, in which he had demonstrated the existence of rhythmical movements in the vena cava of frogs, though he had not observed them in the higher animals. The subject of Dr. Colin's paper was referred to a committee, but that gentleman subsequently remarked that he thought M. Vulpian must be mistaken if he imagined that he had observed these movements to be of a vermicular character. Dr. C. had invariably noticed in his experiments that the contraction operated along the entire length of the sinus of the vena cava at the same time that contraction of the auricles took place. M. Vulpian's error probably arose from his having employed agonized animals.

To this M. Vulpian replied that his experiments had not been made on agonized animals, but on those in whom artificial respiration had been conveniently and carefully sustained.

ATROPHY OF THE TESTICLES FOLLOWING THE USE OF LARGE DOSES OF IODIDE OF POTASSIUM.—The *Gaz. Méd. de Paris*, May 23, p. 269, quotes from the *Pabellou Medico* the following case coming under the notice of Dr. Juan Lomon:

A man of 27 had suffered from various manifestations of syphilis, among others, orchitis and pharyngeal ulcerations. Under the influence of judicious medication by means of iodide of potassium and mercury, all signs of disease disappeared. About a year later, however, some ulceration appeared on the pharynx, and the patient, taking the case into his own hands, dosed himself with large quantities of the iodide. The ulcers were finally healed, but a twelvemonth later he requested Dr. L. to examine his testicles. The right, on inspection, was found to have disappeared; the left was about the size of an almond. Coition was accompanied by pain, erection taking place slowly and lasting a long time. The duration of the venereal act was much prolonged, and no emission of semen took place.

TEST FOR DIGITALIS.—Bonner states that the best test for digitalis is Pettenkofer's reaction with the biliary acids. The smallest trace of digitalis dissolved in water may be detected by the addition, in the first place, of a watery solution of dried bile, and then of sulphuric acid. On warming the fluid to about 160° F., it assumes a peculiar red tint. If the addition of the sulphuric acid be so made that it does not mix with the solution, a red zone appears, which gradually spreads through the whole mass.—*Pharm. Zeitung*, 1873.

PHILADELPHIA MEDICAL TIMES.

A WEEKLY JOURNAL OF

MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY

J. B. LIPPINCOTT & CO.,

715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, JULY 18, 1874.

EDITORIAL.

WHITHER ARE WE DRIFTING?

IN times that are past, the American medical profession was dignified as well as honorable; its leaders men of decorum, whose example was as a bright and shining light that guided the rank and file of the profession in paths of quietness; its code of ethics the reflection of a professional public opinion that bound men together into a united body, leaving a wide gulf between the doctor and the quack. But in the whirlpool of the present decade, the whirlpool whose vortex was the crash of last September and whose eddy is the general stagnation of to-day, the profession at first sight seems to have been swept away from its old moorings,—its reputed leaders joining the mad dance of Mammon, and bartering for gold that professional honor and repute which were formerly valued so highly, or else with dazzled vision mistaking notoriety for fame, and rushing blindly along the paths of the empiric, until medicine and quackery appear to be fusing into one.

Our own city was formerly the very centre of professional dignity,—over-weighted, it may have been, with an excess of that truly valuable but now despised commodity. But what do we see in the present?—newspaper-fame sought after with the greediest avidity by men of the highest position; the college lecture-room turned into an exhibition-room for the juggler, amidst the plaudits of a class only too glad to have their hour of study replaced by the low performance of a variety theatre; grave

professors demeaning themselves to become an appendage of itinerant showmen and performers, playing with them the game of “you tickle me, Tom, I’ll tickle you, Harry,” in the race for advertisement. Frantic, however, as are our struggles, we are ignominiously baffled and beaten by our competitors of a sister city, who, with a genius rivalling that of Paracelsus, ride one sensation after another. As the dog-days approach, the annual cry of “mad dog” affords the opportunity always watched for, and most vehemently has it been embraced.

The particulars of McCormick’s case are, we doubt not, well known to all our readers, certainly so to every one who scans the New York dailies. Although the case at most is only one of hydrophobia, the city is thrown into a turmoil; columns of the newspapers are occupied with the discussions; one day we are told that the great Prof. — is to be at the inquest with his microscope; then that he has been there; then that he has made a wonderful discovery—has laid bare the *fons et origo mali*; and the scientific world is called upon to fall down before him, and to rise to shout hosannas as his triumphal car passes by. The truth seems to be that Prof. — has really done nothing worthy of comment,—done nothing and said nothing which has not been done and said at least as well years before, at home and abroad. A day or two afterwards, a modest card appears, disclaiming the high honors awarded; but has any one a doubt as to who furnished the illustrative diagrams and who inspired the *Tribune* articles? To convert this disgraceful race for notoriety into a comedy only one thing was lacking, and that deficiency was soon supplied. Another professor, not desiring to be completely outshone, taking on himself the duty of a detective, hunts up the dog that bit McCormick, and finds that he was not mad. Here the assistant of the first professor—like master like man—comes on the stage, and, carrying out the search a little further, announces that the dog was certainly not mad, and startles the city reporters and editors with the astounding discovery that any dog, sane or insane, may cause rabies in man by the poison of his bite.

All this may be very funny to read about, but viewed from the old stand-point it is more disgraceful than it is funny. And when the prominent position occupied by these medical Barnums is remembered, certainly the question which heads this editorial will arise in the mind of almost every one. If any, however, will take the trouble to look, we think that he will find that the same names appear over and over again; that really but a few men have seemingly cast aside all the traditions of

the fathers, and that there are still very many physicians, ay, even the great bulk of our leaders, honorable as our fathers would have judged, and wearing robes of unspotted purity. We think, however, that the time has come for a decision as to what the future shall be: whether, adopting the arts of the empiric and of the business-man, the profession shall descend from the position it has hitherto arrogated to itself, or whether it shall bear aloft the old standards of a faith and a practice above that of other walks of life. If the latter is not deemed desirable, by all means let the code of ethics be repealed and the whole profession put on the one footing; but if it is deemed desirable, let the code be enforced.

It may be that these various traps to catch the glitter of notoriety are set so deftly that they are not actual infringements of the code, and no medical society can reach their owners. But there is in every man's breast a longing for respect: even the veriest quack quails in his heart before his own image. If the medical press were always sufficiently independent to raise its voice; if medical public opinion were strong enough and bold enough; if, shunned at societies and avoided in the consulting-room by the individual members of the profession, these medical knights of the daily press felt the loss of respect among their medical brethren; if the records of the lecture-room revealed the damage to the professional standing of the professors,—then these gentlemen would of necessity either pass from one step to another on to open quackery, or, more probably, confine themselves to the legitimate means of obtaining practice.

THE quarrel of *The Clinic* with a British journal seems to have turned the brain of its editor: at least such is the only explanation that suggests itself to us of the following paragraph:

"The *Philadelphia Times* is engaged in a very small business when it throws the whole odium of failure of our national association upon Western men and Western cities. The *Times*, we are sorry to see, feels it necessary to fawningly apologize to Europe by grossly insulting its own country."

All that we said was that the body was not representative of the whole country, and that the larger portion of the best medical profession in America was located in our Eastern cities,—two truisms which could never have excited the ire of any one who was not occupying the position of the Irishman at the fair, who, shillalah in hand, paraded with the request, "Will somebody be plased to tread on my coat-tails?"

THERE are said to be now in Germany eighty-two cremation societies, in as many cities. A furnace, invented by Profs. Reclam and Siemens, of Berlin, is stated to have reduced, at the recent trial, two hundred-weight of animal carcass to white ashes in about an hour and a half, at a cost of three shillings for fuel. Dr. Steinmetz, of Württemberg, has proposed a new method of disposing of the dead. The corpse is to be placed in a trough made of cement, and covered up completely with liquid cement. The cement soon hardens, and, absorbing all moisture from the body, converts it into a preservable mummy at small expense and trouble. As soon as the cement hardens, the square coffins may be piled one upon the other like blocks of stone.

CAREFULLY-EXECUTED casts of the fractured humerus by which the body of Dr. Livingstone was recognized are to be placed in the museums of the Royal College of Surgeons, England, the Royal College of Surgeons, Edinburgh, and King's College, London.

ACCORDING to a law recently passed in Parliament, the question of pregnancy in a woman on trial for murder is no longer to be decided by a jury of matrons, but by competent medical authority.

PROCEEDINGS OF SOCIETIES.

BIOLOGICAL AND MICROSCOPICAL SECTION OF THE ACADEMY OF NATURAL SCIENCES.

JUNE 1, 1874.

DIRECTOR W. S. W. RUSCHENBERGER, M.D., in the chair.

DR. JOSEPH G. RICHARDSON read a paper on "The Value of High Powers in the Diagnosis of Blood-Stains," of which the following is a brief abstract: Observations of the writer, published five years since, have been apparently overlooked by recent authorities, notably Prof. A. S. Taylor, of London, in the new edition of his *Medical Jurisprudence*, so that further investigations seem necessary. The *a priori* arguments against the value of the microscopic test for distinguishing human blood from that of the ox, pig, sheep, horse, and goat, are—1, that the differences between the average size of their corpuscles are too minute to depend upon in a case of life and death; but this objection, valid as regards feebly magnified blood-disks, becomes void when these bodies are amplified 3700 diameters, on the same principle that a twelve-inch shell would never be mistaken for a six-inch shell, even by a careless person who would call a No. 1 a No. 5 shot; 2, it is urged that variations in the size of individual blood-corpuscles are too great and irregular, and too difficult to measure accurately, to render averages reliable; but according to the author's experiments

(especially one in which seven human red blood-disks whose mean diameter had been accurately determined by Prof. Theodore G. Wormley, in Columbus, Ohio, at $\frac{3}{32}$ of an inch, were computed here in Philadelphia to average $\frac{3}{64}$, or only $\frac{3}{32}$ of an inch less than their actual magnitude) this statement is incorrect; and 3, Virchow, Brücke, and their followers think that "a man's life should not be put in question on the uncertain calculation of a blood-corpuscle's ratio of contraction by drying," although a little consideration will show that this is not a fair statement of the point at issue, because, all the blood-disks likely to be mistaken for those of man being normally smaller, instead of *contracting* they would have to *expand* in order to become confounded with those of human blood; and as this expansion does not occur, the only mistake in diagnosis liable to take place is that we might possibly suppose that beef's blood was present when man's blood had actually been shed, so that at the worst we might contribute to a criminal's escape, but *never* to the punishment of a guilty person. To furnish a positive demonstration of the facts of the case, however, the writer obtained from each of his friends Prof. J. J. Reese and Dr. S. Weir Mitchell three specimens of blood-clot from the veins of a man, an ox, and a sheep, selected without his knowledge, and so marked as to furnish no clue as to which animal they were derived from. By the microscopical characters alone he was able to determine with perfect correctness the origin of every one of the six samples; the corpuscles of the human blood chosen by Dr. Mitchell, for instance, averaging $\frac{3}{64}$, with a maximum of $\frac{1}{16}$ and a minimum of $\frac{3}{128}$ of an inch; those of the ox-blood giving a mean measurement of $\frac{1}{16}$, with a maximum of $\frac{1}{8}$ and a minimum of $\frac{1}{32}$; whilst those of the sheep's blood afforded a mean of $\frac{3}{64}$, with a maximum of $\frac{1}{16}$ and a minimum of $\frac{1}{64}$ of an inch. From these and other experiments, Dr. R. concludes his results prove that, since the red blood-globules of the pig, ox, red deer, cat, horse, sheep, and goat "are all so much smaller than even the ordinary minimum size of the human red disk, as computed in my investigations, *we are now able, by the aid of high powers of the microscope*, and under favorable circumstances, to positively distinguish stains produced by human blood from those caused by the blood of any one of the animals just enumerated; and this even after the lapse of five years (at least) from the date of their primary production."

Dr. J. GIBBONS HUNT remarked that he thought these researches really contributed something towards scientific progress, and that it seemed as if the day was not far distant, if it had not already arrived, when we could actually decide, by the aid of the microscope, the important question of the true origin of a blood-stain.

Dr. JAMES TYSON observed that he had been much pleased with the paper just read, but would like to inquire whether admixture of the blood with foreign matters of various kinds, as is so apt to occur in criminal cases, would not so greatly interfere with the detection of blood-corpuscles as seriously to diminish the practical value of the process to a medical jurist. He believed that a weak solution of glycerin, on account of its slight viscosity, approached more nearly to the natural serum of the blood than did the .75 of one per cent. salt solution advised by Dr. Richardson, and, therefore, suggested a fluid composed of twenty fluidrachms of water, thirteen minims of glycerin, and one drop of carbolic acid, as a suitable menstruum for softening blood-stains.

Dr. RICHARDSON replied that the presence of other materials did indeed sometimes render the mechanical part of an examination of blood-stains more difficult

and tedious, but that when accomplished successfully the certainty of the diagnosis was in no wise impaired, since no intermingling with adventitious substances, such as hair or wool, cotton fibres, particles of carbon, or fragments of silica, would, except accidentally, alter the shape or size of the red disks. According to his experience, the most easily recognized blood-stains on clothing were those upon buttons or studs of metallic, pearl, or other hard material, and on paper collars or cuffs; next to these in facility of detection were spots upon starched muslin or linen. Stains upon unstarched linen were harder to discriminate, and the greatest amount of difficulty was met with in an attempt to diagnose stains upon dark or black woollen fabrics. In the recent murder-trial referred to in his paper, the spots were sprinkled upon the legs and feet of the prisoner's coarse cowhide boots, and, contrary to expectation, the blood-disks from these stains, five months after their production, had proved to be quite as easy to recognize and measure as those deposited upon paper collars or cuffs, and of course were very readily distinguished from the oval nucleated corpuscles of pheasant's blood, towards which the story told by the prisoner when first arrested seemed calculated to divert suspicion.

Dr. HUNT stated that Prof. Frey, in his work on the microscope, recommended a fluid called the Pacinian solution, containing a small proportion, about 4 grains to the ounce, of corrosive sublimate, for preserving blood-corpuscles, which would, no doubt, be useful in the manipulation of blood-stains. In regard to the use of high powers, his experience had been that serious loss in definition generally went hand in hand with gain in amplification, so that the more an object was magnified, the more difficult it became to measure it accurately with a micrometer.

Dr. TYSON said he quite agreed with his friend Dr. Hunt in this opinion, since his own experience with a great variety of lenses and eye-pieces to his microscopes led him to incline more and more strongly to the use of low powers.

Dr. RICHARDSON answered that so sure did he feel of being able to demonstrate the very marked difference between the corpuscles of dried clot from the various animals mentioned, under high powers, to *skilled microscopists*, that he would like Dr. Hunt and Dr. Tyson to be appointed on a committee to examine the subject with him and report at some future meeting; not that he expected to convince these gentlemen during such an investigation of his deductions from the facts observed, and especially of the correctness of his doctrine respecting the cellular structure of the red blood-corpuscles; on the contrary, he had no doubt that they would adhere for five years longer, at least, to Dr. Beale's view of the homogeneous, jelly-like nature, or to the German theory of a stroma-like sarcode and a fluid zooid constituent of the red disks; but he felt confident that he could demonstrate to their complete satisfaction that the outlines of human red corpuscles in a dried stain (whether jelly-drops, ækoid stromata, or cell-walls, it matters not to our present inquiry) are nearly twice the size of those of sheep's blood, and therefore readily to be discriminated from the latter when magnified with a power of 1800 diameters.

Dr. HUNT remarked that from the time when these corpuscles of human blood had been first seen by Leeuwenhoek, two hundred and one years ago, they have been the objects of almost constant attention from microscopists, and yet we cannot assert to-day that the structure, the size, or even the shape of the red blood-disk has been positively determined. He had himself seen these appearances in a moistened blood-clot described by the writer, under lower powers, but had placed a different construction upon them, and he was by no means prepared as yet to accept Dr. Richardson's

theory of a cell-wall. Not that he was disposed to undervalue the researches which had just been laid before the Section. On the contrary, as he had previously remarked, there was no doubt that they constituted a real advance in science. The fact that in six different cases the author of this paper had determined the kind of blood without a single error proved that his diagnoses were founded on actual and perceptible differences in the magnitudes of the dried corpuscles, as this accurate discrimination could certainly not in so many instances be the result of mere guess-work. But it should be remembered that Virchow and other earlier observers performed their investigations with inferior lenses. Had they worked with improved tools such as the $\frac{1}{2}$ th and $\frac{3}{16}$ th inch objectives used in these experiments, they would no doubt have made the same discoveries. For his own part, he would like very much to have seen some of the specimens referred to, and to have enjoyed an opportunity of verifying for himself the exact value of this high-power amplification and definition.

Dr. RICHARDSON remarked that he had more than once tried the experiment of showing objects under high powers at our semi-annual exhibitions, and he believed that he would be borne out by other members in the assertion that no one had expressed half the dissatisfaction with his efforts at demonstrating the advantages of a $\frac{1}{2}$ th-inch objective in the hall of the Academy as had his friend Dr. Hunt. He would, however, be very happy to exhibit specimens from these samples of blood-stains at his own house to any of the members present who were specially interested in the subject.

Dr. HUNT replied that the usual summer attendance upon our meetings was so small that he thought the number of members could not decently be urged as a bar to such a demonstration as he had referred to and was desirous of witnessing.

Dr. TYSON suggested that this very difficulty of showing the corpuscular forms publicly—as, for example, to jurors in a court-room—would prevent its being really and practically valuable for the diagnosis of blood-stains in medical jurisprudence.

Dr. J. H. McQUILLEN remarked that some years ago, when engaged upon an extended series of experiments to determine the action of anæsthetics upon the blood-corpuscles, he had examined with low and moderate powers of the microscope the blood of man and of a large number of animals, and also blood-stains in murder cases that had been handed to him by his friend Dr. R. J. Levis. The result of these examinations had made him hitherto very skeptical about the possibility of distinguishing the blood-corpuscles of domestic animals from those of man. He could not, however, deny the value of the experiments just described, and accepted them as conclusive evidence of the possibility of determining this important point. It would, of course, require corroborative evidence on the part of other experienced microscopists where the life of a human being was at stake, but the arguments which had been presented relative to the difficulty of making microscopical demonstrations that would be satisfactory to a jury, although plausible, were open to decided exceptions. He had no manner of doubt that expert testimony grounded on investigations carried on by the observer in the seclusion of his laboratory would be accepted by our judges as valid evidence, even if the expert could not demonstrate his experiments in a crowded court-room. Were it not so, it seemed to him that the whole system of depending upon experts was an error, for who, indeed, was an expert witness but a man who, in consequence of special study of a subject, was better qualified to form an opinion in regard to that subject than were persons ordinarily engaged in other pursuits?

In connection with this matter, he was reminded of an

error that had attracted his attention some time since, when looking over Taylor's Medical Jurisprudence, in the citation of a case in which a man who had been arrested for the murder of an old woman accounted for the blood found on his clothes by stating that he had robbed a hen-roost on the night of the murder, and wrung the heads of the chickens off. The work referred to states that "Dr. Leidy testified from a microscopic examination of the blood alleged by the accused to be chicken-blood that the assertion was false, and the blood was that of a human being."* The correct version of the testimony of Prof. Leidy was that the blood was that of a mammal, and not of a chicken, but he *did not* feel warranted in saying *it was human blood* when the life of a fellow-being was at stake.

Dr. J. G. HUNT exhibited a specimen of the common nettle-leaf (*Urtica*) in which the cystoliths were colored blue *in situ* without any dissection, whilst the remainder of the leaf was tinted violet. He remarked that this double staining of a vegetable tissue in two different colors was an example of a kind of manipulation never, he believed, before attempted or accomplished in the annals of microscopy. It seemed to him that such a capacity for absorbing different dyes indicated that the various portions of the structure were in different vital, or perhaps merely chemical, conditions at the time of their preparation.

MEDICAL SOCIETY OF THE COUNTY OF ALBANY, NEW YORK.

SEMI-MONTHLY MEETING, APRIL 22, 1874.

The PRESIDENT, DR. JOHN SWINBURNE, in the chair.

DR. WILLIAM HAILES reported the following case of *cancer of the liver*. A. B., colored, æt. 75, laborer, came under observation during the latter part of February. He had always enjoyed good health until within the last few months, and it was only within a few weeks past that he manifested much concern in reference to his condition.

He was enabled to work within a month of his death. When first examined, the following symptoms were noticed. Considerable pain was experienced in breathing, followed by a smothering sensation about the region of the heart. His abdomen protruded, and a well-defined tumor occupied a space behind the lower part of the sternum, causing a marked protrusion of the ensiform cartilage upon pressing upon it. The tumor was nodulated, and tender upon pressure, causing spasmodic respiration by embarrassing the action of the heart from pressure. The sounds of the heart were masked, and indicated effusion within the pericardial sac. There was a slight amount of anasarca.

His appetite was good, and his bowels were regular.

The treatment consisted in relieving pain by anodynes, with a nutritious diet.

The symptoms day by day became more aggravated. He died April 2.

Autopsy.—An examination of his abdominal viscera revealed an extensive cancerous disease of the liver, involving both lobes of the organ. It descended a little below the margin of the cartilages of the false ribs, but its greater encroachment was in an upward direction towards the left side, pressing upon and impeding the action of the heart and lungs.

The left lobe of the liver completely filled the hypo-

* A Manual of Medical Jurisprudence, by A. S. Taylor. Edited by Clement B. Penrose, 1866, page 249 (in Commonwealth vs. Armstrong, Philadelphia, 1869).

chondriac space. The stomach and spleen were depressed far below their accustomed space.

The cancerous growth of the liver had gone on to ulceration, and presented a raw and bleeding surface, from which had oozed a large quantity of blood, which was found either floating in clots, or mixed with the serum in the peritoneal cavity.

Section through the organ revealed numberless nodules of a yellow color projecting from the surface, and also occupying deep situations in the liver-tissue.

The liver weighed twelve and a half pounds.

A cancerous mass, about the size of a small orange, was found in the coats of the stomach on the greater curvature, an inch and a half from the pyloric orifice, and was of firm consistence. There were also numerous enlarged and indurated masses scattered over the surface of the great omentum. The mesenteric glands were also considerably involved. From the facts presented, what was the origin of the growth? Did it originate in the liver and extend from this to other organs, or did it first appear in the stomach and from this extend to the surrounding tissues?

We are told that cases of cancer of the liver are of rare occurrence, and that they are usually the sites of secondary growths; that in the majority of cases the stomach is primarily affected, and that it is very unusual for the liver to take on malignant action. Dr. Hailes concluded that the liver was invaded first, from the fact that the disease had made so little headway in the other organs. The hemorrhage seemed to be the immediate cause of death.

The doctor said that there were three ways by which malignancy may infect tissues: 1st, by direct influence upon the adjacent structures; 2d, through the medium of the lymph; 3d, through the medium of the blood. It would seem in this case that it was by the second method that these tissues became involved,—inasmuch as it was confined to so limited an area.

Both kidneys contained numerous cysts; the left having one fully as large as a turkey's egg, besides a number of smaller ones.

Dr. WILLIAM H. BAILEY made the following report of a case of *cancer of the stomach and liver, with peritonitis*. William N. L.; æt. 49; occupation, night-watchman. Early in January, three months ago, he began to notice that he was losing strength. At the same time, pallor of the face appeared, and he had some pain in the stomach, but not so severe as to render it a prominent symptom. He vomited his food occasionally.

The asthenia was most marked. These symptoms came on gradually, increasing until his coming under treatment, March 16.

Further questioning elicited the fact that he had had pain in the epigastrium, with occasional vomiting, for a year back.

He has travelled extensively in all climes, and was in the Army of the Potomac during the war. He had contracted no disease, only receiving an injury in his left eye in the army from a limb of a tree, which destroyed the organ. He has always been a strong, healthy man, excepting that several years ago he contracted intermittent fever, while living adjacent to the city, but recovered on changing his location. His family history was not obtained. Condition when he came to the office for treatment, March 16: His pallor is very marked, there being a yellow tinge. He says he is very weak, and can hardly keep about, being compelled to sit frequently. There is some pain in the stomach, but the symptoms of disease of this organ are none other than might be referred to a moderately severe case of dyspepsia. Examination about the epigastrium reveals nothing. The liver is of normal size. A constant systolic murmur is heard over the heart, plainest at the base,—a roughened, blow-

ing sound. The action of the heart is regular. There is no enlargement of the spleen or of the lymphatic glands, these being examined with a view to the possibility of the case being one of leucocythæmia. With the same idea, the blood was examined microscopically, but no increase of white blood-cells was detected, though the examination was not altogether satisfactory. On the 21st of March he sent word that he was unable to visit the office. The night previous, he vomited freely a brown, coffee-colored fluid, which was noticed as being much more abundant than the ingesta. There was no much pain, and when visited in the morning he was seemingly quite comfortable. For four days he improved, having little pain, though vomiting frequently, and, although weak, was able to walk a few blocks. His vomiting was relieved by a mixture of sweet spirit of nitre, paregoric, and soda, and small quantities of fluid food were retained.

His countenance was always cheerful. On the morning of March 25 he felt better than any time since the 21st. His chief complaint being debility at this time, his blood was examined microscopically; the least attempt to take food provoked an attack of vomiting; his cough then set in and continued all night, in spite of remedies, leaving him prostrated in the morning. He craved cold drinks constantly, which aggravated the vomiting.

Dr. Swinburne was now called in consultation. He was inclined to believe a little thickening could be detected at the epigastrium.

The symptoms, however, left no doubt in the minds of the physicians who saw him that the malady was cancer of the stomach. After the 25th, the pain was much more marked and constant, with more tenderness on pressure. He retained his cheerfulness throughout.

There was no febrile action, prostration and pain expressing all his symptoms for the next three days, at the end of which he died.

Autopsy, twenty-four hours after death.—There was pallor of the whole body, no waxy or dusky tinge being observable. Emaciation was marked, and the muscles were very flabby. But little rigor mortis.

On opening the abdominal walls there was found over the stomach a quantity of thick, yellow pus, and there was evidence of peritonitis affecting the gastric and diaphragmatic peritoneum. A cancerous mass surrounded the pyloric end of the stomach, extending along the lesser curvature for one-third of its length: this appeared broken down on the external surface, a spot of the size of a silver quarter having the look of an ulcer. This was probably the cause of the peritonitis. On the inner surface of the stomach there was still more breaking down of the cancer-tissue. The pyloric orifice was open, admitting the passage of the little finger.

The stomach was greatly distended, and contained two quarts of coffee-colored fluid. This mass of diseased tissue was about the size of the first, and was completely covered in front by the left lobe of the liver. The whole mass was very firm. Part of the pancreas was adherent and included in it. There were also deposits of cancer-matter, of the size of a walnut and less, throughout the liver. These seemed comparatively recent, and none of them protruded above the surface of the organ. The liver was not enlarged; weighed three and a half pounds. One mesenteric gland was enlarged and very hard; calcareous.

Other abdominal organs were entirely healthy; the spleen quite normal in size and structure.

The heart was somewhat enlarged, and there was a patch of atheromatous deposit on its surface. The coronary artery was entirely calcified. The aortic valves were not competent, and were thickened. A fibrinous clot, sixteen inches long, extended up the aorta.

The lungs were healthy. The brain was also found healthy.

The deposits in the liver and stomach were examined by Drs. Vanderveer and Balch, and found to be true cancer.

In this case the diagnosis, though quite certain towards the last, and placed beyond a doubt by the autopsy, was somewhat marred by the absence of one or two almost constant symptoms of the disease.

There was no tumor of the epigastrium. This is said by Da Costa to be the only symptom at all distinctive of cancer of the stomach. The case is very instructive, not only in the absence of this symptom, but in the cause for its absence being found. The thin left lobe of the liver covered the cancer completely, preventing all possibility of any evidence of the tumor, which really existed, being obtained by palpation.

Pain is usually another symptom, and perhaps as constant as any other next to tumor.

This peculiar pain of cancer,—lancinating, piercing, sharp,—which we feel ought to be experienced in all cases of cancer-growth, is not always present when the deposit is in the stomach-walls. In fact, I believe the general verdict is that there is nothing distinctive about it here. It was not augmented by food, I believe: so far as the stomach-symptoms went there was little to indicate the existence of anything more than chronic indigestion or subacute gastritis, the latter being rendered more probable by the fact of his having been a rather intemperate man. As concerns this symptom of pain, it was not made prominent at all by the patient in giving his history. Vomiting was a symptom from the first. This was more characteristic of the disease than either of the others mentioned, especially considering the nature of the matter ejected. Persistent vomiting is suggestive of cancer, but not diagnostic. Cases are mentioned of thickening about the pyloric orifice causing it, and so also do *sarcina ventriculi*, pregnancy, sometimes ulcers, etc. But I suppose that, in cases of irregular vomiting lasting several months, cancer should be first thought of. The coffee-ground matter, too, is, if thrown off for a long time, characteristic. In gastric ulcer, blood is vomited in abundance if at all, and not in this particular form. The pallor exhibited in this case is indicative of the cancerous cachexia; so, too, it is of anæmia. There was nothing peculiar about it; nothing of the yellowish tinge spoken of as that of this cachexia.

The marked weakness, which was one of the three prominent symptoms from the first, had nothing in it peculiar to cancer. It was this weakness, with the pallor and the heart-murmur, which was at first thought to be anæmic, which led to the thought of leucocythæmia. But examination detected no enlargement of the spleen or liver, or of the lymphatic glands, and no increase in the number of the white blood-cells was found by the microscope.

Taken together, the pallor, the continued vomiting of coffee-colored fluid, and the tired feeling or weakness, may be looked on as sufficient upon which to base a diagnosis of cancer of the stomach, even in the absence of any marked pain or of the tumor in the epigastrium usually spoken of as the most constant symptoms of cancer of the stomach.

Dr. JAMES S. BAILEY gave the following report of a case of cancer of the *pancreas, liver, mesentery, and uterus*. C. B., German, æt. 36, mother of five children, the youngest 3 years old. She menstruated at the age of 14, and was always regular and enjoyed good health until November last, when she visited the cemetery while her catamenia were upon her. She sat on a cold, damp stone, and walked through the wet grass; she contracted a cold, and her menses ceased. She was seized with pain in the back and abdomen, which

resembled labor-pains. She still menstruated regularly until in February, when it ceased. Since that time she suffered more pain, particularly after eating.

The abdominal recti muscles were separated from over-distention, and two ridges were seen longitudinally over the region of the ovaries. She rapidly emaciated, and experienced a throbbing sensation in the left inguinal region, as if an abscess was forming. She complained of great weight on standing. Simpson's sound, being introduced, revealed the length of uterus to be two inches. Its mouth was flabby and open; and on the anterior and posterior portions were plainly felt tumors of some size.

There had been a tendency to constipation; there was also a smarting, burning sensation in the region of the womb.

My first visit was made June, 1873, several other physicians having attended her previously. She died in July.

Autopsy, twenty-four hours after death.

Body much emaciated. Rigor mortis marked. Skin had a general cachectic appearance. The right lung was bound down with numerous adhesions to the costal pleura, and the cavity on this side contained eight ounces of serous effusion. Left lung normal. Pericardial sac contained a small amount of serum. Stomach healthy.

On the outer border at the bifurcation of the trachea there was a deposit of carcinomatous matter, which on pressure exuded a blackish-looking fluid. The pancreas was imbedded in a homogeneous mass, having the appearance of malignancy. The mass was hard and indurated. There was also a constricted mass in almost the whole of the mesentery; in such small portions of the mesentery where a like condition was not evident, the glands were enlarged and softened. The colon and meso-colon contained upon the anterior coats a similar mass. The walls of the ascending colon were considerably thickened, and deposits of the same character were found in them constricting the intestinal canal.

The liver was small and pale, with normal capsule. In the upper part of the right great lobe there was a circumscribed portion, about one and a half inches in diameter, of a like character with that found in the mesentery and intestine. The kidneys were small and flabby, otherwise normal.

The peritoneal cavity contained about a pailful of a greenish-looking fluid.

Upon the anterior and posterior aspects of the uterus was found a mass of like character to that found in other parts of the body. The recto-vaginal tract was filled with the same mass, being felt through the rectal walls as a hard indurated tumor. The same condition was found behind the peritoneal layer of Douglas's cul-de-sac.

The left ovary was normal; the right ovary hard and indurated, and about two inches in diameter. On its upper and outer sac it contained a small cyst, the walls of which were easily ruptured.

Bladder empty.

Microscopical examination.—Several specimens were examined from different organs. Large giant-cells were found, and the diseased condition is evidently of a carcinomatous nature.

Dr. ALBERT VANDERVEER reported the following interesting cases of *cancer*, and exhibited the pathological specimens.

Case I.—*Cancer of the Stomach*.—M. C., married, æt. 71, temperate habits for the last twenty years, had had occasional sharp pains in the region of the stomach, and at times would vomit food. Yet he considered that he was in good health, and was enabled to attend to his business,—that of a carpenter.

I saw him first January 10, 1874. He has been in decided ill health for the past year, failing in flesh and strength, suffering severe pains in the stomach, and most of the time vomiting his food. For the past month his stomach has not retained anything, and only during that time has he been confined strictly to his house. He appears very much emaciated, and extremely pale and cachectic.

In the epigastric region I can define a hard tumor the size of a goose-egg, painful to the touch, producing when handled a sensation of extreme weakness and a desire to vomit.

Some œdema of the feet. Lungs and other organs appear healthy. Urine examined: specific gravity 1020, acid; no albumen, and a fair quantity passed in twenty-four hours. Ordered small doses of morphine, to be administered with a bitter tonic, also subnit. bis. and pepsin.

The latter acted well, but he could not bear the tonic and anodyne. There was no improvement in his case, —none was expected. Death occurred on January 19, 1874.

Autopsy, twenty-four hours after death. Rigor mortis marked. Decided emaciation; no general anasarca; slight swelling of the feet. Lungs and heart in a healthy condition. Very light pleuritic adhesions, and slight atheromatous change in inner coat of large arteries.

The coats of the stomach, from the cardiac to the pyloric opening, were thickened in some places as much as two inches; the deposit scirrhus in character. The cavity of the stomach was almost completely obliterated, and yet the passage through its orifice continued open.

It could not hold more than an ounce of fluid. In some places the mass had softened, and presented points of ulceration. The great omentum was filled with hardened masses, from the size of a pin's head to that of a cherry. Spleen normal; capsule shrunken; adhered decidedly to great end of stomach. Pancreas not diseased. Liver normal. Kidneys normal. Intestinal canal from pyloric orifice to anus in a healthy condition. Slight effusion of serum in peritoneal cavity. Scrotum on examination presents double hydrocele, and on a more careful examination each testicle is the seat of a cancerous deposit; the one on the right quite large. Head not examined.

Case II.—Cancer of the Stomach.—L., married, æt. 62, good habits, always in excellent health excepting one severe attack of cystitis ten years ago, but after six months' illness made a good recovery. Came to the office December, 1872, presenting a decided case of jaundice, for which he desired treatment. Gave him alteratives alternately with tonics until January 12, 1873, without any improvement in his case. Constant failing in strength and flesh, with little vomiting. Has continued to work until the present time.

Decided to stop work, remain home, and seek other medical advice. A careful examination revealed decided tenderness over the liver, but did not detect any tumor in the epigastric region.

April 21, 1873, again solicited to see the patient with his attending physician; in the interval he has consulted many doctors, but his disease has been gradual and certain in its advance. Is a mere skeleton in appearance, and very weak; presents the same deep jaundiced condition as when last seen. It is difficult to define the borders of the liver; a hardened mass is felt over the region of the stomach. Of late he has vomited everything. Urine on examination is found loaded with bile, and is scanty in quantity. Died April 25, 1873, from inanition.

Autopsy, eighteen hours after death. Muscles rigid,

—what little is left of them. Encephalon not examined. Organs of the thorax healthy.

The pyloric end and about one-third of the stomach were found to be the place of deposit of a cancerous mass as large as a good-sized orange, flattened. The pyloric orifice of the stomach was closed from the inflammation and ulceration present. The cancerous mass also enclosed a portion of the pancreas, all the vessels going to and from the liver, and a portion of the duodenum. The liver was about half its natural size, and filled with nodules of cancerous growth. The gall-bladder was shrunken, containing about one drachm of bile. Spleen very small, but healthy. Omentum studded with hardened masses of various sizes. Kidneys healthy; no traces of inflammation about the bladder. Testicles not examined.

Case III.—Cancer of the Testicle.—W., æt. 65, suffered for the past fifteen years from hydrocele on the left side of scrotum. Has been tapped many times. During the past year the testicle has become quite hard, much enlarged, and pains him constantly. His general condition has been good, but now, from want of sleep and the intense pain he suffers, he is failing in strength. Is willing to undergo any operation that will promise relief. Has a large scrotal hernia on the same side. In consultation with his attending physician, Dr. Newcomb, October 12, 1873, we decided to remove the testicle, which was done. The rupture gave us some trouble, but, notwithstanding, the patient made a good recovery in three weeks.

The testicle is as large as a goose-egg. The tunica vaginalis is very much thickened, but the inner part of the mass is found on microscopic examination to be encephaloid in character. The structure is so changed that it is impossible to define any portion of the testicle proper. The patient at the present time remains in good health, with no symptoms of the disease returning.

Case IV.—Cancer of the Liver and other Organs.—M. A., æt. 44, married, mother of four children, usually in good health. Lost the left eye from disease two years ago. Family history good. Not well nourished; is over-anxious to provide a home for herself and family, and denies herself much in food. Is somewhat jaundiced; bowels constipated, with failing strength, yet does her own house-work; menstruates regularly; is troubled much with nausea; is growing thin in flesh, and does not sleep well, and complains of much pain in the right side.

On examination, a distinct enlargement of the right lobe of the liver can be felt, extending downward and inward towards the umbilicus. Is very hard to the touch, and percussion gives acute sickening pain. No disease of any other organ can be detected. Ordered tonics, nourishment, rest, and anodynes sufficient to relieve pain. Was called to attend the patient August 17, 1873. At November 1, the patient had continued in about the same condition, but occasionally vomited her food. The enlargement had extended down towards the inguinal region, and on a level with the navel.

February 1. Has just passed a menstrual period, but is now not able to leave her bed; is much emaciated; skin darkly jaundiced; can retain but little food in her stomach; suffers greatly from pain. Enlargement is much increased, and of a stony hardness.

Bowels move once in four days; fæces of a light clay color. Urine is passed quite freely, and is high-colored. A tumor about the size of a butternut can be felt in the left breast, also one much larger surrounding the sternal end of the left clavicle. These tumors feel very hard, and give her much suffering. Death occurred March 16, 1874. She did not menstruate after February 1. Is a mere skeleton; all of the soft tissues

are apparently absorbed. Has been able to retain but little of anything in her stomach for the past three weeks; bowels not moved during that time.

The enlargement of the liver fills almost the entire abdominal cavity. The tumor in the left breast has increased in size, while the breast itself seems entirely absorbed: in fact, the tumor and nipple are all that can be defined. The tumor of the clavicle has included the greater portion of the bone. Another tumor, of the same stony hardness, has developed in the right breast. The jaundiced condition of skin has increased. She appears much like one suffering from an attack of Addison's disease. The flow of urine has been very scant of late. Mind was clear until death.

Though every inducement is offered, and every argument advanced, yet the consent of her family to hold a post-mortem cannot be obtained. Case believed to be one of cancer of the liver and other organs.

Case V.—Cancer of Duodenum and Pancreas.—Mrs. C., æt. 49, had enjoyed good health up to two years ago last May; Dr. Vanderveer saw her for the first time, July 29, 1873. Her menstrual periods then ceased, and she noticed soon after that her food, after eating, gave her some distress. She was married, and was the mother of two children, both living. An aunt died of some cancerous affection; her family history is otherwise good. She appears pale, and has an anxious expression.

Ten months ago she began to vomit food, with also a black, coffee-colored fluid in large amounts; and for the last two months this has been a very troublesome symptom. The bowels are constipated; there is considerable pain in the epigastrium and the right hypochondriac region. A distinct tumor can be felt at the lower end of the pyloric orifice of the stomach. The urine is normal. Ordered subnitrate of bismuth, and enemata to empty the bowels twice each week, with anodynes to relieve pain.

December 1, 1873. Mrs. C. has been more comfortable, does not vomit so much, and gets more rest, but is failing in strength and flesh. There is a decided cachexia present; a marked yellowness also of the skin, more prominent at times. Takes very little food. From this time until death, she was kept quiet by morphine.

There was no more vomiting, although she ate freely. *Post-mortem* held January 30, 1874.

Rigidity well marked; body extremely emaciated; mesentery attached to abdominal walls; stomach partially filled with liquids, apparently healthy throughout its whole extent. There is a hard mass, the size of a turkey's egg, about three inches below the pyloric orifice of the stomach in the duodenum, including its walls; also a portion of the pancreas. Left lung adherent; cicatrix in the apex of left lung. Cicatrix in upper part of right lung. Edges of liver rounded; parenchyma normal. Small amount of effusion in pericardium. Heart normal. Kidneys normal. Encephalon not examined.

Microscopical examination of diseased portions shows an abundance of giant-cells with nidus and well-marked stroma.

Case VI.—Cancer of the Stomach.—Mrs. V.; æt. 66; widow. While attending another member of the family, my attention was called to her condition, September, 1872. Has been confined to the bed for the past two years, and for the three years previous had been troubled with dyspepsia, as she had been told. Accounts of family history not clear, nor of the time of her change of life. Is now too feeble to give her history. Is merely skin and bone. For the past two years has vomited much dark-looking fluid and the most of her food. Her daughter states that for the past two months she has absolutely refused to take anything into her

stomach, dreading the vomiting and distress that followed. Is sure that she has not taken an ounce, all told, in that time. A hardened mass can be felt at the pyloric end of the stomach. Bowels not moved in two months. Died November 1, 1872.

Post-mortem, twenty-four hours after death. All of the organs in the body were in a healthy condition, except the pyloric orifice of the stomach, and this was closed and surrounded by a hard scirrhus growth, not larger than a butternut, and not yet in a state of ulceration, but completely closing the stomach.

Case VII.—Cancer of Œsophagus.—W. M., æt. 62, April, 1873, came for treatment for inability to swallow. On examination with œsophageal tube, could detect a decided stricture about four inches down, through which only the smallest-sized bougie will pass. Looks pale; has lost in flesh, and is weak. Œsophageal bougies of various sizes were passed twice a week, until the largest could be passed. The relief was marked up to June 10, 1873, when, in withdrawing the largest one, he complained of some pain and raised a trifle of blood, while in the shoulder of the instrument could be seen several pieces of a fleshy-looking substance, which was examined under a microscope, and exhibited small cells and spindle-shaped cells, with nuclei, after which the use of bougies was discontinued. When informed that his case was believed to be one of cancer, he became disheartened, and begged to have the instrument passed for temporary relief. Was confined to his house two months previous to his death, not able to swallow much of anything. Suffered some pain, though it was not acute. No family history obtained.

His habits had been bad for the greater part of his life, and for the last ten years he had been a steady drinker.

Autopsy.—Cachectic appearance; body emaciated; abdomen collapsed; rigidity marked. The right elbow-joint much enlarged. Several of the costal cartilages are ossified.

Thorax.—There are adhesions of the upper and posterior portions of right lung to the pleura costalis. Two ounces of effusion in right pleural cavity. Right lung crepitant and healthy throughout its whole extent. Four ounces of effusion in left pleural cavity. Left lung not adherent at any point; parenchyma healthy throughout the whole extent. Some hypostatic congestion.

In about the middle of the œsophagus the walls anteriorly and laterally are ulcerated through, excepting a small band of tissue which divides the two. The pyloric and cardiac orifices of stomach healthy. Stomach contains about 3ii of a dark, grumous-looking fluid. Coats normal. Pericardial sac contains about an ounce of serum. Heart normal in size. Parenchyma firm; semilunar valves normal; mitral valves healthy; considerable atheromatous change in the descending aorta. Large fibrinous clots extending from the right aorta into the right ventricle and into the arteries. Tricuspid valves healthy.

Abdomen.—Liver nine inches long, seven and a half inches broad, three and a half inches thick. Hepatic tissue atrophied and yellow in appearance; appears shrunken and hob-nailed; edges rounded and shrunken. Gall-bladder full; spleen much enlarged, seven inches long, four and a half inches wide, two inches thick. Its surface is studded with small prominences. Some of the mesenteric glands are somewhat enlarged and of a dark, congested appearance. Left suprarenal capsule healthy. Left kidney normal in size. Cortical portion appears granular and roughened. Capsule thickened and adherent at points. Right suprarenal capsule is abnormal, and contains numerous deposits. Right kidney of the same general character as the left one. Bladder contracted.

Microscopical examination of diseased portion of oesophagus reveals it to be encephaloid in character.

Case VIII.—Peritonitis from Ruptured Ovarian Cyst.—Dr. John M. Bigelow was called, March 6, to see Mrs. W., æt. 58. She had been complaining of great pain in the right iliac region for seven or eight days previously. Her symptoms pointed to peritoneal inflammation, as indicated by tympanitis and pain and tenderness on pressure, with the symptoms usually found in diffusive peritoneal inflammation.

From the time the first symptoms were manifested until death took place, was twelve days.

Post-mortem made by Dr. A. Vanderveer. Head and organs of the thorax not examined. There was an immense deposit of fat in the abdominal walls. A crucial incision was made, and on turning back the flaps the intestines were observed to be greatly distended with gas. The great omentum extended down, and was adherent, by recent bands of false membrane, to the upper surface of what we first supposed to be a distended bladder. The lower portion of the omentum was very much discolored with recent infiltration of blood. The folds of the small intestines in the right inguinal region were adhering together by lymph, the result of recent inflammation. No deposit of pus found elsewhere, nor any other distinct signs of peritonitis.

On separating the lower part of the omentum from the supposed distended bladder, the latter was found to be an ovarian cyst from the left broad ligament. The pedicle was about three inches in length, and twisted upon itself; in the act of twisting, a blood-vessel had been ruptured, and the blood had infiltrated the walls of the cyst and the lower part of the omentum.

On opening the cyst, it was found to contain a quart of bloody-looking fluid, which does not coagulate on standing. Other organs of the abdomen healthy. The peritonitis undoubtedly resulted from the twisting of the pedicle of the tumor and effusion of blood from the ruptured blood-vessel.

REVIEWS AND BOOK NOTICES.

A TREATISE ON FOOD AND DIETETICS. By F. W. PAVY.

This volume of nearly six hundred pages certainly affords sufficient space to say all that is at present worth saying in regard to the medical aspects of the food-question. The literary work is well done; the style, though not strikingly terse, is free from verbosity, and there are many parts which are worthy of high commendation from a scientific stand-point,—notably the general discussion on the rôle played in the economy by the nitrogenous alimentary principles and by the carbohydrates. We must, however, state our conviction that the book does not fill the want that exists for a complete, thoroughly scientific, and practical work upon the subject. It contains an enormous amount of very curious but utterly useless facts, and omits very many things that are of the utmost importance. The long chapter, for example, upon "Animal food sometimes but not ordinarily eaten," shows a very wide range of reading in its author, but seems to us of no practical value. What use is it at the bedside to know that a black man tastes more salt than does a white man, and is therefore better eating, or that monkeys are eaten by the Chinese, the natives of Ceylon, the Indians, and so on through a long list of tropical savages, white and black and copper-colored? In the same way the chapter upon "Fruits" is largely wasted space. We

do not want to be misunderstood: if a scientific author chooses to put such material in his book, we do not complain; it has a curious interest, if not a practical value. What we object to is the omission of matters of vital importance, and the stuffing of space, which their discussion ought to occupy, with the merest padding for an idle moment. In the work before us some of the most vital subjects of the hour are avoided, and their place filled up with these jottings of desultory reading. Practically nothing is said in regard to the value of want of value of beef-tea, or the physiological action of tea and coffee, and the discussion on alcohol is almost childish in its feebleness.

We do not want to be too severe upon the work of Dr. Pavy, or in any way to express an unfair judgment, but we think those of our readers who are acquainted with Dr. Letheby's little volume upon the same subject will agree in believing that it contains at least as much of value as its very much larger and more pretentious rival. In conclusion, we may express the hope that when the present work reaches its second edition the author may well use the great room there is for improvement, and bring the whole volume to the level of the parts first mentioned in this notice; and when this is done, the emendated book shall have our highest praise.

THE PRIZE ESSAYS OF THE BOYLSTON MEDICAL SOCIETY FOR 1874. I. Experiments on the Action of Bile in Promoting the Absorption of Fats. By CHARLES H. WILLIAMS, A.B., of Boston. II. On Intestinal Digestion. By G. M. GARLAND, A.B., of Lawrence. Pamphlet, 8vo, pp. 26, with Two Plates. Reported from the *Boston Medical and Surgical Journal*.

In these essays we have some of the first-fruits of the new method inaugurated scarcely three years ago at the Harvard Medical School. They emanate more directly from the Physiological Laboratory of the school, under the direction of Dr. H. P. Bowditch, Asst. Prof. of Physiology. They are creditable alike to the school, Dr. Bowditch, and their authors.

We have not space to describe the process or apparatus used, though in the case of the first subject both are somewhat different from those employed by previous experimenters, but append the conclusions. Those of Mr. Williams are as follows:

1. That the passage of neutral fats through capillary canals or pores is favored by the presence of bile in these pores.
2. That this action is increased when the bile is rendered alkaline, and diminished when it is acid.
3. That the action cannot be due to the bile changing the form of the pores.
4. That after passing through membranes moistened with bile, the fats appear more finely divided than with membrane wet with other substances, apparently showing that the drop-tension or cohesion of the fat has been affected.

II. Mr. Garland followed Thiry's method of isolating a portion of intestine by excision and leaving its attachment to the mesentery intact.

Like Thiry, he found the quantity of intestinal juice secreted by the isolated loop exceedingly small,—from five to fifteen drops in an hour.

From experiments with the juice he concluded—1, that intestinal juice converts starch into sugar; 2, its action upon boiled white of egg is doubtful; 3, whether alkaline or acidified, it exerts a solvent influence on fibrin; 4, its action was increased by combining it with a 0.2 per cent. solution of hydrochloric acid, while Thiry declared that intestinal juice when acidified ceases to act upon fibrin; finally, he observed that fibrin was converted into peptones by the action of hydrochloric acid alone.

ANATOMY OF THE INVERTEBRATA. By C. TH. V. SIEBOLD. Translated from the German, with Additions and Notes, by WALDO I. BURNETT, M.D. James Campbell, Boston, 1874.

This book appears to be a reprint from stereotype plates of the well-known translation of Von Siebold which appeared in 1853; the original German edition having been published in 1848 or 1849. The book is too well known to need comment from us, but we can commend it to every one who is desirous of posting himself upon the subject treated of as known a quarter of a century ago.

PAPERS CHIEFLY ANATOMICAL. By BURT G. WILDER, M.D., Prof. of Comp. Anat. and Zoölogy, Cornell University, New York. Salem, Mass., 1874.

These memoirs are of the purest science, and therefore, although most creditable, and a just source of pride to every American, have but little interest to the "busy practitioner." The only one directly connected with medicine is upon a double human monster, with a very interesting note and figure of a dicephalous Peruvian mummy.

GLEANINGS FROM OUR EXCHANGES.

THE PREVENTION OF HYDROPHOBIA.—*The Lancet*, in its issue of May 23, editorially discusses the question of the best means for securing the public safety during the season when rabies is prevalent among dogs and other animals. The discouragement of the breeding of useless dogs, by a rigid system of licensing and the compulsory use of numbered collars, would do much towards diminishing the number of accidents. It has been proposed to render dogs harmless by cutting off and filing down their canines and incisors. Experiments have shown that when rabid dogs, whose teeth had been filed down, were allowed to attack healthy animals, no communication of the disease occurred, and the author of the system (M. Bourrell) claims that its general adoption would extirpate hydrophobia, by rendering its transmission impossible. The use of the muzzle should be vigorously enforced, but it should be of such a description as to admit of free respiration and the exposure of the tongue to the air.

The most effective preventive measures are perhaps those which could be easily applied by owners of dogs if a reasonable watchfulness were exercised and the animal were placed under restraint on the first appearance of premonitory symptoms.

For days before a dog becomes savagely rabid he manifests certain peculiarities of demeanor, hiding in obscure corners, swallowing indigestible substances, sometimes gazing intently as though watching the movement of some object on the ground, now and then snapping at anything which is presented to him, and altogether behaving with an eccentricity which attracts notice, although it is seldom referred to its cause. After a time the dog is missed suddenly, and never seen again. The owner deplores the loss, and never suspects that the creature, in obedience to a resistless impulse, has rushed away on its mad career, and, if it has escaped the sticks and stones of the excited populace, has at length crawled into some dark place and died. It is not much to ask of owners of dogs that, in the interests of the community, they should remember the possibility, to say the least, of these animals becoming the subjects of a terrible malady, which, being communicated to man, is certain to result in death in the most hideous form: a lifelong regret will not compensate for a calamity which watchfulness might have prevented.

ANTIDOTE OF RABIES (*The Lancet*, June 6, 1874).—Dr. Jitzki communicated, in January, 1874, to the Imperial Society of Wilna (Russia), a fact of some interest. A very savage dog was in the habit of killing vipers (*Coluber berus*), and his mouth and neck were covered with wounds inflicted by the vipers. This animal was bitten by a mad dog which had already bitten several horned cattle and a dog; these all perished in a rabid state. The owner of the first-mentioned dog, not wishing to destroy him, determined, however, to watch him, and made up his mind to kill the poor animal at the first symptom of rabies. Nothing, however, happened, and the dog remained quite well.

This case struck Dr. Jitzki, especially as he learned that a woman of the same locality had been bitten by a viper and some time afterwards by a mad dog without suffering from hydrophobia. He was thus led to suspect that there is antagonism between the virus of hydrophobia and the virus of vipers. If this were true, young dogs might be inoculated with the latter virus, and thus be made insusceptible to hydrophobia.

FORK-SWALLOWERS.—"L'homme à la fourchette est le héros du jour." This seems the opinion of the French press, and the case itself is of interest and has given the excuse for the recital of numerous similar cases. He is a lad of 18, a shop-boy, who had been fascinated by the tricks of a juggler who swallowed swords, knives, and forks. The last trick he had imitated a dozen of times, when one day the fork slipped from between his teeth and could not be got hold of. A doctor caught its end with a pair of dressing-forceps, but the attempt at removal gave the patient so much pain that he had to let go: the fork slipped into the stomach, and the pain was at once relieved. M. Labbé, under whose care the patient is, has proved the presence of the fork in the stomach, by an examination by a special sound under the influence of chloroform. The sound has a sounding-board apparatus attached to it. No attempt at interference has as yet been made.

M. Baillarger has reported a case in the *Union Médicale* of a lunatic who swallowed a fork, and lived six years with it in his stomach. He had walked with a peculiar stooping gait, and tried to avoid sudden shocks. It was found at the autopsy, with the points at the cardiac end of the stomach.

M. Loscoles de Lozère tells M. Labbé of the case of a lady, who, in 1824, swallowed a fork, which was well borne for six months. It then began to cause pain and swelling in the stomach, and eventually was cut out by M. Quairoche with perfect success.

M. Le Tellier reported, in the *Revue de Thérapeutique* in 1853, the case of a suicidal female, who, after various unsuccessful attempts, managed to swallow a fork. It gave no trouble for four years, when intense pain and abscesses in the thigh heralded its appearance after a long journey from the stomach. The greater part of it was removed from the trochanteric region, but the patient died exhausted.

Dr. Charpy, of Lyons, saw the following. A female lunatic, æt. 56, swallowed a fork, told of it, was not believed, till after some days a tumor was felt in the right iliac fossa, which increased in size, became red, with adherent skin, eventually bursting and giving issue to a large fork twenty days after it was swallowed; for fifty-five days air and débris of food came through the wound, which eventually healed up.

M. Dureau has written to the *Gazette Médicale* an interesting and elaborate note of remarkable substances found in the stomach. From this we extract the following bearing on the fork question. Mr. Lund's case of recovery after passing a dessert-knife from an abscess close to the umbilicus is an allied case. Dr. Chemin's case, reported by Velpeau to the Academy

of Sciences in 1849, was that of a man who, trying to force down a veal-bone which had stuck in his throat, swallowed the fork by accident. It remained fifteen days in the stomach, four months in the pyloric end, three months in the small intestine, and eventually was passed by stool, much diminished in size. The patient recovered.

M. Foville records at great length, in the *Gazette Hebdomadaire* (No. 18, 1874), two rather curious cases in which one maniac swallowed *seriatim* the whole of a set of dominoes with which two old gentlemen had been playing, while they were taking a short walk in the garden, and passed them all again by stool; while another, in a state of religious fervor, swallowed his beads, to which a cross was attached, and passed it also entire without injury.—*Edinburgh Medical Journal*.

THE DANGER OF MIXING CHROMIC ACID WITH GLYCERIN.—In preparing mixtures of this kind, which have been so highly recommended for diseases of the mouth and throat, care should be taken not to add these reagents together too quickly, for it is said that the fluid may take fire and explode. There is no danger if the glycerin be added drop by drop, for then a little warmth only will be generated.—*Il Raccogl. Med. Memorabilien*, 2, 1874.

MISCELLANY.

A LATE agent on the San Carlos reservation relates the following: "The Indian Department are in the habit of issuing on certain days rations for each man, woman, and child; and on one of these occasions a crowd was assembled around the agency awaiting their turn, when a little commotion was noticed among the squaws, one of whom was seen to lie down on some hay on the ground, while others gathered around, the cause of which was explained in a few minutes by the screams of an infant. In less than half an hour the mother claimed a ration for the little stranger."

Such is woman in her *wild* though *natural* condition. A bad community for a doctor, you will doubtless say.—*B. G. McPhail, M.D.*, in *The Clinic*.

DEATH OF AN INFANT FROM THE APPLICATION OF AN ACETATE OF LEAD LOTION TO THE NIPPLES.—M. Bouchat mentions the case of a lady who, having used a lotion called *Eau de Madame Delacour*, a favorite quack remedy in Paris for sore nipples, omitted to wash it off before putting the child to her breast. The child was shortly after seized with violent colic, and died in a few days with all the usual symptoms of lead-poisoning.—*Gazette des Hôpitaux*.—*Boston Med. and Surg. Journal*.

SPONGY iron is produced by calcining powdered iron ore with charcoal. Such iron forms a most excellent filter, more powerful, it is said, than even animal charcoal. It is said that even sewage-water filtered through a layer of this substance is completely purified, and will remain sweet for almost an indefinite time.—*The College Courant*.

DR. LEVIS having resigned his connection with the clinic upon diseases of the eye at the Jefferson Medical College, Dr. William Thomson is now sole lecturer upon the subject at the institution named.

ACCORDING to one of our exchanges, if a horse be rubbed with a mixture of fifteen drachms of assafœtida in one tumbler of vinegar and two of water, the flies will not annoy him. The same object, it is stated, can be obtained more cheaply by anointing the animal with a small quantity of the oil of laurel.

NOTES AND QUERIES.

DEATH OF DR. JAMES McNAUGHTON.

Dr. James McNaughton died in Paris, June 19, from heart-disease. He had gone abroad, accompanied by his wife and two daughters, to visit the home of his boyhood in Scotland. Six years ago his fiftieth anniversary in the practice of medicine was celebrated in the Albany County Medical Society. He had lectured in medical colleges for more than half a century. At the time of his death he was President of the Albany Medical College, and Professor of the Theory and Practice of Medicine. He was the oldest teacher in medicine living.

He was born on the Grampian Hills, in Perthshire, Scotland, in 1796, and at the time of his death was seventy-eight years of age. Prepared for college at Kenmore, Dr. McNaughton was admitted to the University of Edinburgh in 1812, and graduated in the medical department in 1816. He then accepted a position as surgeon on an emigrant-ship to America, and while the ship was waiting he visited some relatives in Albany, who persuaded him to resign his position and locate in the practice of medicine in that city. He determined to do so, and soon took a prominent position in the profession. Three years later he was appointed a lecturer on anatomy at the College of Physicians and Surgeons at Fairfield. The next year he was appointed to the Chair of Anatomy and Physiology, and continued to lecture for nineteen years on these subjects. In 1840 he was made Professor of the Theory and Practice of Medicine in the Albany Medical College, a position he filled with great credit until his death.

He had completed his fifty-third course of lectures, and during this time had not missed a dozen lectures.

Dr. McNaughton was known as a contributor to the various medical journals. He was a tall, hale-looking man, with courteous and genial manners. Prof. Christison, of the University of Edinburgh, is believed to be the next oldest living lecturer: he began in 1838.

A special meeting of the Medical Society of the County of Albany was held in the council-chamber, City Hall, July 2, 1874, to take suitable action in reference to his death. The attendance was very large, and, in the absence of President Swinburne, Dr. Thomas Hun was called to the chair.

Eulogies upon the deceased were pronounced by several members, and the following resolutions adopted:

"*Resolved*, That this Society has lost not only the eldest, but also one of its most respected and valuable members. We deplore his loss, and we sincerely mingle our sorrows and regrets with those of the dear ones in the desolate home.

"*Resolved*, That we attend his funeral in a body, and wear the usual badge of mourning, and that a copy of these resolutions be transmitted to the family of the deceased."

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY, FROM JULY 1 TO JULY 13, 1874, INCLUSIVE.

RANDOLPH, J. F., SURGEON.—Assigned to duty as Post-Surgeon at Camp Robinson, Wyoming Territory. S. O. 90, Department of the Platte, July 3, 1874.

BYRNE, C. C., SURGEON.—Granted leave of absence for six months, with permission to go beyond sea. S. O. 145, A. G. O., July 3, 1874.

BROWN, J. M., ASSISTANT-SURGEON.—Assigned to duty as Post-Surgeon at Plattsburg Barracks, New York. S. O. 131, Military Division of the Atlantic, July 8, 1874.

VICKERY, R. S., ASSISTANT-SURGEON.—Assigned to duty at Little Rock, Ark. S. O. 102, Department of the Gulf, July 6, 1874.

O'REILLY, R. M., ASSISTANT-SURGEON.—Assigned to duty as Post-Surgeon at Fort D. A. Russell, Wyoming Territory. S. O. 90, c. s., Department of the Platte.

HALL, J. D., ASSISTANT-SURGEON.—Leave of absence extended thirty days. S. O. 147, A. G. O., July 7, 1874.

SATURDAY, JULY 25, 1874.

ORIGINAL COMMUNICATIONS.

ON THE RELATION OF ELECTRICITY TO THE PAIN OF HERPES ZOSTER.

BY A. D. ROCKWELL, M.D.,

Electro-Therapeutist to the Woman's Hospital of the State of New York.

HERPES ZOSTER, if not the most persistent, is, without doubt, attended by the most excruciating pain of the various neuroses of the skin. Whether its seat be the head, the trunk, or the extremities, the associated pangs are sometimes almost beyond human endurance.

"Imagine," says one of its victims, "the marrow taken out of the bones of your arm, a rough towel threaded through them, and two devils at work with all their strength at each end of the towel sawing it backwards and forwards: that is what the pain is like." Herpes is now generally regarded as subordinate to the existence of a neuralgic or rheumatic diathesis, and as originating in any cause which weakens the vigor of a nerve-trunk or its cutaneous branches: hence it would not be unreasonable to suppose that electricity in some one of its forms might prove of service.

The teachings of experience so clearly attest its value in this complaint that I cannot hesitate to put on record the following cases, in all of which, without exception, the treatment adopted was entirely successful. The disease, it is true, runs an acute course, and, as a rule, recovery more or less complete follows in the course of a few weeks, but it is none the less incumbent to relieve, so far as possible, the acute sufferings that attend it. Local applications are of little avail, and the latest considerations in regard to allaying the neuralgia of zoster do no more than recommend the administration of opiates and the bromides.

The first two cases which I briefly record occurred in that part of the body—viz., the trunk—which is said to be the most frequent seat of the disease. The succeeding three are of somewhat greater interest, because of the comparative infrequency with which such cases are met.

ZOSTER THORACICALIS—TREATMENT BY THE FARADIC CURRENT.

Case I.—Jane A., a dispensary-patient, aged 7 years 6 months, had suffered for several weeks from febrile symptoms and anorexia, and finally erythematous patches appeared on the chest and right side. The eruption increased and rapidly extended, until the thorax was nearly encircled. The pain from which the child suffered was very severe, and for forty-eight hours it had been continuous. I employed general faradization (mildly), and was rewarded by an immediate relief of the neuralgic pains.

Four similar applications were subsequently given,—one on each alternate day; but there was no return of pain, and within ten days the eruption, which resembled aborted vesicles, had quite disappeared.

ZOSTER SACRALIS—TREATMENT BY THE FARADIC CURRENT.

Case II.—I was called, December 3, 1873, to see a gentleman aged 34, who was suffering from an herpetic

eruption over the region of the sacrum. The vesicles extended from the hip to the sciatic notch on the right side, and covered a narrow tract along the outer portion of the thigh, with clusters here and there to the external malleolus. The accompanying neuralgic pain was quite as severe as in the preceding case, and simulated actual sciatica. I placed the foot of the patient on a copper plate, to which the negative pole was attached, and with a mild faradic current brought the whole hip and limb under the electrical influence. The effect was most grateful, and the relief afforded immediate.

The same method was repeated a number of times, and although the patient occasionally experienced twinges of pain, they were of little severity, and within a week ceased to annoy him.

ZOSTER FRONTALIS—TREATMENT BY THE GALVANIC CURRENT.

Case III.—A lady aged about 60, and sent to me by Dr. C. R. Agnew, had suffered long and severely from zoster of the forehead and face. Acute and persistent neuralgia supervened, resisting all attempts at permanent alleviation. The galvanic current was locally and centrally applied, and resulted, in a few sittings, in relieving in a good measure the neuralgic pains. Ptosis of the right eyelid remained, however, in spite of the treatment by galvanization. Three local applications of the faradic current approximately restored the lost muscular power.

ZOSTER FRONTALIS—TREATMENT BY BOTH FARADIC AND GALVANIC CURRENTS—ALLEVIATION OF PAIN ONLY BY THE GALVANIC CURRENT.

Case IV.—Mrs. L., aged 39, consulted me on June 10, 1874, and gave the following history of her case. Two weeks prior, her attention was called to a small vesicular eruption on the left forehead, directly over the course of the supra-orbital nerve. Similar eruptions quickly followed, thickly studding the side of the head and face, and accompanied with much pain. A homoeopathic physician had had the case in charge, and had succeeded in temporarily relieving the neuralgia only by the administration of morphine. When the patient fell under my observation she was suffering more than at any previous time, and, rather because of convenience than choice, I gently applied the faradic current to the affected and surrounding parts. It caused neither during the application nor subsequently any special modification of the distress. On the following day I resorted, as I should have done at first, to the constant current, making the applications locally and by the central method, and in less than ten minutes the intense agony of the patient was almost completely relieved. She passed a very quiet night, but in the morning complained of some distress over and in the right eye and temple. She was immediately relieved by a second application, after which she was subjected to treatment several times, although she suffered but little if any, and rapidly progressed towards recovery.

ZOSTER FRONTALIS—TREATMENT BY THE GALVANIC CURRENT.

Case V.—A third case of zoster frontalis, in the person of a female aged about 35, fell under my observation on the 2d of June last, through Dr. Beard, who transferred it to my care.

The lady, who was a patient of Dr. Oliver White, first observed a slight eruption over the right eye. This rapidly spread until the whole side of the head and face to the angle of the mouth was involved. The associated neuralgia was of the most excruciating and intolerable character. Dr. L. Bulkley was called in consultation, and advised the constant current, a few applications of which rapidly and effectually relieved the patient of all pain, and greatly hastened recovery.

It will be observed that of the above cases the first two, in which the eruption was confined to the body, were relieved by the faradic current; and that the three following (herpes frontalis) yielded to the galvanic current.

The differential indications for the use of the two forms of electricity, although now tolerably well understood, are far from being reduced to fixed laws. In the matter of the relation of electricity to pain especially there is a wide diversity of opinion, and while there can be no doubt in regard to the general superiority of galvanization to faradization in the relief of pain, there is a manifest tendency to underrate the value of the latter in this respect. Its boundaries of usefulness are not nearly so narrow as might be supposed from much of the writing that has lately appeared on the subject; and it is surprising that any one who has had much experience in electro-therapeutics, and whose observations have been directed with any degree of care, should relegate the use of the faradic current in cases of pain to purely hysterical and pseudo-neuralgic conditions, and account for the *rationale* of its effects solely on the principle of counter-irritation. It does not, however, come within the scope of this short paper to discuss the relation of electricity to pain in general. I would merely point out what seem to me legitimate conclusions from the above experience in the treatment of herpes:

1. That the pain of herpes, no matter where the seat of the eruption may be, is generally susceptible of speedy and effectual relief by the use of the galvanic or faradic current.

2. That when the eruptions take place on the head the galvanic current alone has power to relieve the pain.

3. When the disease is confined to the trunk or the extremities, the faradic current will relieve pain and hasten recovery, and is preferable to the galvanic.

CHOLERA INFANTUM.

BY HARVEY L. BYRD, M.D.,

Professor of Diseases of Women and Children in the College of Physicians and Surgeons of Baltimore, Md.

THIS terrible scourge of infancy and childhood is carrying large numbers of the young and tender ones of this community to their long homes, and such is the extent of its ravages that it might be said with propriety of language to prevail at this time as an epidemic in our midst.

Baltimore, hygienically considered, is probably the equal in all, or at least very many, respects to her most favored sister-cities; but, while this is the case, the hand of the destroyer occasionally falls heavily upon her, and she is then called upon to mourn the loss of those she cannot rescue from the embrace of death. Since the advent of summer the mortality has been considerable among infants and children one to three and four years old, but it is chiefly

within the last three weeks that our mortuary tables exhibit a fearfully large proportion of death from cholera infantum. Within this period there has been not only a steady but an alarming increase in the death-statistics from this generally intractable and fatal malady. After resorting to the remedies most in vogue in the treatment of *summer-complaint*, such as calomel in minute and moderately large doses, alone and in combination with Dover powder, chalk, charcoal, etc., bismuth, magnesia, pepsin, tannic and gallic acids, acetate of lead, alum, nitrate of silver, creasote, pyroligneous acid, laudanum, etc., etc., alone and in various combinations and mixtures, with indifferent or unsatisfactory results, even when strict attention was given to diet, fresh air, bathing, stimulants when called for, etc., it was finally decided to adopt a plan of treatment with special reference to an alterative action on the blood; at the same time giving strict attention to the skin with a view to the elimination of the poison, as far as might be, by this organ.

Accordingly, with this leading object in view, namely, an appeal to the blood primarily, sulphite of sodium and aromatic sulphuric acid were prescribed internally, and tepid or cold alkaline baths, according to indications, ordered externally, to which whisky or brandy was added when required.

One grain of the sulphite, with four drops of paregoric, was given in gum-water every two hours, to a child one year old, and the dose doubled for a child two years old, increasing or lessening it according to age and the anodyne effects of the paregoric, thus:

℞ Sulphite of sodium, grs. xvi;
Pulv. g. acac., grs. xii;
Tinct. op. camph., fʒi;
Water, ʒij.—M.

Sig:—One teaspoonful every two hours, to a child one year old, shaking the phial before using. One drop of elixir vitriol in three teaspoonfuls of iced water was given, three times a day, to a child one year old, and the dose increased one drop for each year and lessened to one-fourth or one-half drop when below one year of age. A tepid or cold bath, rendered alkaline with an ounce or more of carbonate of sodium, potassium, or common salt, was used morning and night. In addition to the foregoing remedies, aromatic cataplasms were ordered, and kept applied over the entire stomach and abdomen. Cow's milk and farinaceous articles of food not to be allowed, and scraped or finely-chopped beef, or lamb, raw or but partially cooked, or essence of beef (to which a small portion of brandy is to be added when required by the feebleness or prostration of the patient), used as much as practicable as nourishment. Wine-whey allowed freely in the second stage of the disease, when it agrees with the patient. Infants were allowed the mother's milk, or that of a healthy wet-nurse, and fifteen to twenty drops of lime-water three or four times a day when the milk disagreed. This plan of treatment has been pursued for the past two weeks, with complete success. In a small proportion of cases, quinine, in appro-

priate doses, was also administered when a tendency to periodicity was observed.

Several of our confrères have been advised of this plan of treating cholera infantum as it exists in this city, and are satisfied with the results. It is proper to state that all the cases of the disease that have been treated thus far by the writer have been among the well-to-do and better classes of the community. Long experience in the treatment of epidemics of various kinds, particularly those of yellow fever, cholera, cholera infantum, etc., has satisfied your contributor that no single plan of treatment, however successful at one time, can be relied upon in all epidemics of the same kind, nor during the same epidemic in all cases; but he feels, nevertheless, that the demands of humanity and duty to a common profession conspire to prompt this communication to the readers of the *Medical Times*, so that such use of the remedies may be made in their cases as they may think proper or expedient in the future.

The course of treatment above detailed having thus far met the reasonable expectations of all the parties interested, it is devoutly to be hoped that no such modification or important change in the character of the prevailing epidemic may take place during its continuance as may render it less efficacious or successful in the future than it has proven up to the present. On a subsequent occasion the writer may venture to give publicity to views and opinions he now entertains on the causes and pathology of this indigenous and fearfully destructive enemy of the Caucasian race, as found in the larger cities of this continent.

BALTIMORE, July 9, 1874.

TWO EXPERIMENTS UPON THE INFLUENCE OF LARGE DOSES OF QUININE UPON PREGNANT ANIMALS.

BY H. C. WOOD, JR., M.D.

THE subject of the uterine action of quinine is of the greatest practical importance, and is certainly in a very unsettled state. There have been very few experiments with it upon pregnant animals published, and the opportunity for such trial of it does not offer very frequently. For these reasons I have thought the following experiments are worthy of being recorded, and offer them without further comment.

Experiment I.—A female cat in a very advanced stage of pregnancy, but evidently not quite at full term. At 12.30 P.M. twenty grains of quinine were injected into the cellular tissue of various parts of the body. At 1 P.M. the cat offered no symptoms worthy of remark. At 2 P.M. she was seen by my assistant, and was alive. At 4.30 P.M. I found her dead and rigid. She had not aborted, and there were no indications of any disturbance of the genitalia.

Experiment II.—A cat, apparently at the end of her pregnancy. At 2 P.M. ten grains of quinine were given hypodermically. The next morning the cat was seemingly in exactly the same condition as before the injection, and was used for another experiment.

NOTES OF HOSPITAL PRACTICE.

PENNSYLVANIA HOSPITAL.

SERVICE OF J. AITKIN MEIGS, M.D.

Reported by FRANK WOODBURY, M.D.

TYPHILITIS AND FECAL ABSCESS.

THE following are the notes of a case admitted to the Pennsylvania Hospital during the service of Dr. J. Aitkin Meigs, by whose kind permission the case is reported.

In addition to the interest ordinarily attached to cases of perforation of the vermiform appendix, this case possesses some special features worthy of remark, in that there was an almost entire absence of symptoms up to the onset of collapse, and no clue could be obtained by whose aid a diagnosis could be established or rational treatment instituted.

The case was No. 629, laborer, æt. 23, single, born in Saxony, and was admitted to the men's medical ward July 7, 1873. The following history was obtained from those who brought him. He had apparently been in ordinary health until two days before admission. He then complained of pains in his back and abdomen, loss of appetite, and weakness, but continued at his work until noon of the day of admission, when he fell to the floor, without premonition, in a state of syncope. On regaining consciousness, presently, he commenced to vomit. This vomiting persisted, his stomach even rejecting ice-water, which he constantly requested to quench his burning thirst. His comrades now decided that he was sick, and brought him in a wagon to the hospital.

When admitted, his knees refused to support him as he was assisted to bed, and he was mildly delirious. He babbled of green fields and of cool streams, and wanted to bathe in the clear water. But he was easily aroused, for, being asked a question in German, he indignantly requested that he might be addressed in English, curtly coupling it with the information that he had been long enough in the country to understand the language.

His decubitus was dorsal, without flexion of the limbs. The face was cadaverous, eyes sunken, nose thin and pinched, complexion sallow, lips bleached, all suggesting collapse. The pulse was slow, somewhat irregular, moderately full and compressible. Breathing irregular and sighing. The surface of the body was cool and clammy. The vomiting after admission was simply by regurgitation, the fluid flowing from his mouth without effort or retching. He did not complain of pain anywhere, but suffered principally from thirst. His bowels were constipated.

As he was apparently sinking, some hot whisky and a stimulating enema were directed to be given, and heat applied to the extremities; but he died in less than half an hour from admission.

At the autopsy, the lungs were found to be normal. The heart contained a fibrinous, "chicken-fat" clot. The left ventricle was contracted; the semilunar valves were normal, but both the mitral and tricuspid leaflets were thickened, and bound down by old inflammatory adhesions. Liver small, dense, and in its external appearance was bluish like the spleen. Internally they both were dense, and contained but little blood. Gall-bladder distended with yellow bile. The kidneys were small, capsules adherent, no morbid condition noticed. In the peritoneal cavity was a quantity of offensive yellow pus and a serous fluid. The peritoneum was discolored, the omentum thickened, and the small intestines bound together by bands of recent lymph. The appendix vermiformis presented an extremity made

patulous by ulceration, and was the centre of a large abscess, which had been limited by adhesions, but had recently burst into the general peritoneal cavity. In this abscess two small bodies were found, and a third was still in the embrace of the appendix. These strongly resembled, and at first were pronounced to be, cherry-stones, but on section they looked more like allspice or juniper-berries.

They were sent to Dr. J. G. Richardson, who, after microscopic examination, pronounced them to be small masses of fecal matter.

TRANSLATIONS.

INTRAVENOUS INJECTION OF CHLORAL IN SURGICAL OPERATIONS.—M. Bouillaud read before the Académie des Sciences (*Gaz. Méd. de Paris*, May 16, 1874) an account of the following operation recently performed by M. Oré, in which chloral injected into the veins was the anæsthetic used. The patient, who was about to suffer resection of the calcaneum, had a solution of chloral (of the strength of one part to three of water) injected slowly into the radial vein of the right arm.

By the time three drachms had been introduced, the patient declared that he felt very sleepy. The injection was pushed until five and a half drachms of solution (about 115 grains chloral) had been introduced, when the patient suddenly fell into a profound slumber, accompanied by almost cadaveric rigidity.

The time required to produce this effect was about ten minutes. The operation, involving the usual incisions, required about twenty-five minutes for its performance.

During the whole of this time the patient slept calmly, made no cry nor complaint, while the perfect immobility of the limb denoted complete annihilation of sensibility. Respiration continued calm and regular, and showed none of those spasms of asphyxia which were observed when similar injections had been used in tetanic cases.

When the operation was finished, the interrupted current from a strong battery was used to restore the patient to consciousness, one pole being placed on the side of the neck and the other over the epigastrium. Under the electric influence the respiration became freer, and in a few moments the patient sat up and conversed, though wildly, as if intoxicated. This condition lasted an hour, followed by floods of tears. Shortly after, he sank into a natural sleep, and waked later in the day in his usual condition.

M. Oré's conclusions are as follows: 1, a solution of one of chloral to three of water is sufficiently strong for the purpose of intravenous injection; 2, the injection should be made after direct puncture, without laying bare the vein, in order to avoid all risk of coagulation or phlebitis; 3, the injection should be made slowly, so as to test the idiosyncrasy of the patient; when sleep is produced it is unnecessary to continue the injection, for the anæsthesia will persist in a manner never brought about by chloroform; 4, the operation terminated, it is possible, by means of electric currents, to cause the condition of immobility to cease on the instant. The surgeon should have at hand from the beginning an electrical apparatus in good working order. If the anæsthesia produced by intravenous injections of chloral be applicable to surgical operations, it will be found exceptionally advantageous in operations of long duration, such as resections and ovariectomy.

A. V. H.

HERPES ZOSTER FOLLOWED BY INTERCOSTAL NEURALGIA AND LOCAL SWEATS.—At a recent meeting of the Société de Biologie (reported in the *Gaz. Méd. de Paris*, May 16, p. 258) M. Ollivier communicated the notes of a very interesting case recently under his care. The patient, an old man, had suffered from an attack of herpes zoster on the right thorax, running on to ulceration about a year previous to his admission to the hospital. Two months subsequent to this attack he began to experience lancinating pains in the chest on the affected side, coming on at intervals at first, then becoming almost continuous and more severe. The neuralgia affected the sixth, seventh, eighth, and ninth intercostal spaces. Treatment consisting of morphia, dry cups, blisters, etc., was unavailing.

When admitted to the hospital, a year after the onset of the disease, he seemed in tolerably good health to all appearances. A few scars on the right side of the chest showed the former locality of the eruption. Persistent lancinating pain still existed in the locality referred to; pressure at any point in the intercostal spaces caused severe pain. Abundant sweats were observed over the whole affected region, becoming more marked during the neuralgic attacks.

Some months later, the patient began to experience still more severe pain, localized at the point of emergence of the intercostal nerves of the sixth space; the skin became immovable over the affected side, and the patient's general surface assumed a sallow hue. He lost flesh from this time rapidly, and died rather suddenly after having been under observation about a year.

No physical signs had been observed in the chest excepting great faintness of the respiratory murmur and a want of mobility on the affected side. The post-mortem examination showed extensive carcinoma of the pleura and lung on the right side, with similar degeneration of the intercostal nerves.

GASTROTOMY IN LESIONS OF THE STOMACH AND INTESTINES.—The *Gaz. Méd. de Paris*, Nos. 17 and 20, 1874, gives extracts from an article on this subject by Dr. Boinet in the new *Dictionnaire Encyclopédique*. Dr. B. gives a number of cases illustrating the various lesions and methods of operation, particularly in cases when foreign bodies have been swallowed. He maintains that operations performed on the stomach are not necessarily fatal nor resultant in fistula; sutures may be used with success. Death has frequently occurred from the escape of alimentary or other matters into the abdominal cavity, an accident which may be avoided by using the same care as in an ordinary case of ovariectomy.

Dr. B. concludes that in cases when such foreign bodies as forks, etc., have been swallowed, operative interference is strongly to be advised. He also gives some practical directions in regard to incisions, sutures, etc.

A. V. H.

TROPHONEUROSIS.—M. Lancereaux (*Gaz. Méd. de Paris*) read before the Société Méd. des Hôpitaux at a recent meeting the notes of a case of exfoliative dermatitis of the extremities following an affection of the nervous centres, with painful irradiations in the diseased parts. The patient, a woman 37 years of age, had suffered from right hemiplegia with aphasia, brought on by painful emotion. After lasting some months, the affection became somewhat ameliorated, and at the end of a year only a certain feebleness remained, with some alteration of vision. About this time she was attacked by constricting pains around the waist, and pains in the continuity of the limbs, knees, and feet, accompanied by nutritive disorders. At the time of her admission to the hospital she had also paralysis of the third pair. The pains in her limbs were sharp and lancin-

ating, and were more severe when she attempted to walk. Tactile sensibility and sensibility to pain were intact.

At the same time that these nervous phenomena were being developed, certain alterations in the skin of the extremities were manifested. The skin of the plantar and dorsal surface of the feet became red, infiltrated, and covered with white scales somewhat resembling those of psoriasis. The toe-nails became lengthened, and the epidermis upon the toes much thickened. In some places small fissures covered with yellow crusts might be perceived. The alteration was symmetrical, but more developed on the right than on the left leg, which later became the seat of more painful attacks, while the cutaneous alterations grew here more decided. There appeared on the right leg at the same time an erythematous patch, smooth, uniformly red, accompanied by tumefaction and heat, sore to pressure, and offering, in a word, the characters of an erysipelas or rather of an area of angioleucitis. In addition, the inguinal glands were tumefied and painful. This patch disappeared after a few weeks, leaving after it a sallow-gray tint of the skin, which was covered in this place with scales and remained thick and hard. Soon after, an eruption resembling syphilitic psoriasis appeared on the right wrist and palm of the right hand; afterwards an eruption of similar patches appeared on the left wrist. In spite of bromide of potassium, arseniate of iron, etc., the disease progressed, the appearances on the skin extending up the legs and arms, the lymphatic glands themselves participating in the morbid process. The patient subsequently died, but no post-mortem examination was obtained. The hybrid nature of the skin-disease and its *pari-passu* progress with the paralysis led M. Lancereaux to conclude their intimate connection.

A. V. H.

THE INFLUENCE OF ANÆMIA ON THE NUTRITION OF THE MUSCULAR TISSUE OF THE HEART (*Virchow's Archiv*: Dr. Leopold Perl).—When hemorrhage is sudden and profuse, death occurs from paralysis of the vital nerve-centres, due to a want of sufficient oxygen to enable them to continue their functional activity. In cases of chronic anæmia which are due to repeated losses of blood, part of the symptoms which occur, and sometimes the fatal issue, are to be attributed to this same cause. The explanation of another train of symptoms must be looked for in the altered relations in regard to their relative densities between the tissues and the blood. From this results œdema of various parts, and among those in which œdema produces the most serious results are the lungs and brain. A third group of symptoms, which has not been adequately studied until quite recently, comprises such as result from fatty degeneration of parts of the circulatory system.

Some years ago Virchow noticed that in the variety of anæmia to which the name chlorosis is given there was an incomplete development of the blood-vessel system, and, further, that there was frequently in these cases some fatty degeneration, which was more particularly noticeable in the muscle of the heart and in the internal coat of arteries.

Gusserow has quite recently published the results of his observations upon the hearts of several women who suffered from the anæmia of pregnancy in a marked degree, and he found, as a constant companion of other alterations, some fatty degeneration of the substance of the heart. In numerous cases of anæmia of high grade, occurring for the most part in young females, to which the name "progressive pernicious anæmia" was given, in addition to the many symptoms of an altered state of the blood which were noted during life, at the autopsies of such cases as died under observation a similar state of the cardiac tissues was found.

Ponfick, who has had excellent opportunities of examining cases in which this connection of anæmia and fatty heart co-exists, has established the fact that an analogous degeneration occurs in the hepatic and renal cells, and in the cells of the tubular glands of the stomach. Dr. Perl claims that this degenerative process has a general signification, and regards the alterations which are noticed in the heart as but one result of a general process which results in similar degenerations in other organs; and in support of this view he was able to show the existence of a high grade of anæmia in almost all cases in which the characteristic fatty degeneration was found.

In 92 per cent. of his cases he was able to assign as a cause for the appearances seen at the autopsy either some chronic and exhausting disease, as typhoid fever, some affection of the digestive tract, by which absorption and nutrition were interfered with, or, finally, repeated losses of blood. To establish this last point, the connection between repeated losses of blood and fatty degeneration in particular organs, but more especially in the heart, Perl performed numerous experiments upon dogs. In choosing dogs for the subjects of his experiments he was obliged to draw his conclusions from the conditions observed in the muscular tissue of the heart, for in animals of this species which are apparently in good health it is not uncommon to find fatty degeneration of the parenchyma of the liver and kidneys, while the muscle of the heart is rarely altered and the transverse striæ of the muscular fibre are distinctly marked. Before commencing the experiments, and after the bladder and rectum had been emptied of their contents, the dogs were carefully weighed. A superficial vein was then dissected out with as little disturbance as possible to the surrounding tissues, a ligature was applied, the vein cut, and a sufficient quantity of blood allowed to escape. The animals were divided into two classes, from one of which larger quantities of blood were drawn at longer intervals, while from the second smaller amounts were taken, but more frequently. From those of the first class, at intervals of five to seven days, blood to the amount of three to three and a half per cent. of the weight of the animal at the time of the experiment was taken, and from the others, every three to four days, one to one and a half per cent. of the weight. The condition of the heart was found at the examination made after the death of the animal to be very different in the dogs of the two classes mentioned above. In the majority of those which had been subjected to large losses of blood at prolonged intervals, the only palpable organic change which could be discovered was a well-marked disturbance of the nutrition of the heart, while in those of the other class in which the loss of blood had not been carried sufficiently far to be attended with fatal results, nothing of this kind was seen.

Perl thinks that the results of his experiments justify the conclusion that there exists a relation of cause and effect between anæmia and the changes of nutrition observed on the heart. The results of his experiments are strongly confirmed by the cases referred to above, in which fatty heart was found both in patients who had succumbed to chronic diseases, and in those who had been exhausted by repeated losses of blood.

W. A.

MEDICAL PROPERTIES OF THE AILANTHUS (*The Druggist's Circular and Chemical Gazette*, July, 1874).—Dr. Robert has found that in hot climates an infusion of the bark of the root of ailanthus is a valuable medicine in dysentery, giving results superior to those of ipecacuanha, calomel, and astringents, either with or without opium; it is also preferable to the treatment by milk.

THERAPEUTIC NOTES.

VAPOR OF HOT WATER IN THE TREATMENT OF CON-GENITAL ATELECTASIS.—Dr. Kjellburg (*Trib. Méd.*, 1874, p. 428) places the little patient in a sort of vapor-bath, which he makes by disposing of the bed-covers by means of hoops, etc., in such a manner as to form a sort of cell, into which the vapor from a vessel of boiling water is conducted. The temperature of this enclosed space should not range below 77° F. nor above 86°. The atmosphere should be frequently renewed.

In this hot and humid medium the respiration becomes much more free, the bronchial secretions no longer accumulate in the air-passages, the temperature of the body falls, and the appetite improves.

The duration of the bath, as well as the degree of humidity, varies according to the gravity of the case, and may be graduated accordingly.

Sometimes the treatment has to be continued during eight to twelve days. Dr. K. has cured by this means not only pulmonary atelectasis, but also various laryngeal and bronchitic troubles in infants at the breast.

INHALATIONS IN ASTHMA.—

R Ætheris sulph., pts. 30;
Acid. benzoic., " 15;
Bals. Peruvian., " 8;

or, according to another formula,

R Ætheris sulph., pts. 2;
Sp. terebinthinæ, " 15;
Acid. benzoic., " 15;
Bals. Peruvian., " 8.

Place the mixture in a vessel having a large opening; the warmth of the hand is sufficient to volatilize the materials, and inhalations may be used four or more times a day as occasion demands.

FOR PAINFUL HEMORRHOIDS.—

R Ext. hyoscyam.,
Pulv. saffron, aa ℥ijss;
Plumbi acetat., ℥i;
Glycerole of starch, ℥i.—M.

FOR CHRONIC ECZEMA.—

R Sodii carb.,
Oleum cadini,
Picis, aa ℥ss ad ℥i;
Axungiae, ℥vijss.—M.

TREATMENT OF GRANULAR PHARYNGITIS.—An extract from the *Bull. de Thérap.*, in *L'Union Méd. du Canada*, March, 1874, gives Dr. Cousin's method of treating this affection. Dr. C. states that general remedies suited to the diathesis should be employed as well as local applications. He prefers gargles to inhalations, excepting where there are laryngeal complications.

Tar-water, or water impregnated with sulphurous acid, may be employed, though Dr. C. prefers a solution of some simple saline, common salt for instance, with perhaps the addition of glycerin. Solutions of alum, he thinks, destroy the enamel of the teeth. If the inflammation has reached the naso-pharyngeal cavity, it will become necessary to use the nasal douche. The pharynx may be touched with small pledgets of cotton or lint, dipped in Mandl's solution of iodo-iodurated glycerin (one per cent.), or of pure glycerin.

In scrofulous ulceration of the throat, especially in phthisical patients, a solution of equal parts of chromic acid and water may be applied by the same method. The patient should gargle with some neutral fluid or water immediately afterwards, and the application should be made twice weekly.

CROTON CHLORAL IN NEURALGIA.—Croton chloral has been used by Dr. Jules Worms in various cases of neuralgia and other painful affections with considerable success. Dr. W. uses larger doses of the remedy than are usually administered. He thinks it inadvisable to be given hypodermically. The following formula resembles the one usually preferred by him:

R Croton chloral, ℥ii;
Glycerin.,
Aquæ, aa f℥i f℥vi;
Syrupi, f℥iv;
Ol. menth. pip., gtt. iii.—M.

Sig.—Tablespoonful every three or four hours.

ULCERATION OF THE NOSE IN SCROFULOUS CHILDREN.—M. Galezinsky is accustomed to treat ulcerations of the cutaneous surface generally in these cases by dusting them with calomel, with appropriate internal treatment. When similar ulcerations form in the nares, he recommends similar applications, or occasionally the following ointment:

R Hydrarg. ox. rub., gr. iv;
Camphoræ pulv., gr. iss;
Axungiae, ℥i.—M.

STYPTIC COLLODION.—

R Tannin, ℥ii;
Alcohol, f℥iv;
Ether, f℥xij;
Gun-cotton, ℥i ℥ii;
Canada balsam, ℥i.

Dissolve the tannin in part of the alcohol and ether, the Canada balsam in another part, and the gun-cotton in a third. The solutions are then mingled.

MILK IN THE TREATMENT OF CHRONIC DYSENTERY.—Dr. Barrett (*L'Union Méd. du Canada*, March, 1874), who has been studying for some time the action of milk in the treatment of chronic dysentery, adopts the following method of administration. The milk should be pure, without any admixture with water, and as fresh as possible. The patient placed upon this fluid as a diet should take absolutely no other nourishment, no other medicine.

The first effect noticed is the great abundance and fluidity of the stools; this is of short duration,—a few days at most. When the fecal discharges begin to be more solid, the administration of subnitrate of bismuth, with occasionally the addition of chalk-mixture, hastens the process. Occasionally, while using bismuth, in persons who have been enfeebled by long-continued discharges, certain scorbutic purpura-spots are observed: this symptom is best combated by the use of citron-juice. Should a bilious flux manifest itself later, mild cathartics, such as manna or the sulphate of sodium, may be employed.

Occasionally the milk may not be digested, and may show itself in the stools in a grumous form, indicating want of power in the digestive fluids. In this case pepsin (gr. v t. d.) will supply the deficiency and render the milk perfectly assimilable. Vomiting of the milk, which occasionally occurs, may be prevented by the same means. Of course, when convalescence sets in, care must be redoubled to prevent a relapse.

At first, condensed milk, white of egg, milk-soup, may gradually be brought into use; then boiled fish, eggs, and easily-digestible meats may gradually lead the way to the ordinary diet, the milk being continued throughout.

Every care should be taken to guard against infractions of diet. Occasionally, especially when the milk is poorly digested, lime-water may be added, in the proportion of one part to two or three of milk.

PHILADELPHIA MEDICAL TIMES.

A WEEKLY JOURNAL OF

MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY

J. B. LIPPINCOTT & CO.,

715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, JULY 25, 1874.

EDITORIAL.

THE ARMY BILL.

AS no doubt most of our readers know, during the last days of the recent Congress a bill was finally passed regulating some of the staffs of the army, and including the medical department. As the matter may have a personal interest to some of our subscribers, and must have a general interest to all, we extract from the *Congressional Globe* that section of the bill which relates to the medical department, adding also, by way of contrast, that portion which affects the ordnance corps. We call attention to the circumstance that in the latter the number of generals, colonels, lieutenant-colonels, and majors is to that of the lower grades as 18 to 36, whilst in the medical corps the proportion is as 55 to 150.

"Section 4. That the Medical Department of the Army shall hereafter consist of one Surgeon-General, with the rank, pay, and emoluments of a brigadier-general; one assistant-surgeon-general, and one chief medical purveyor, each with the rank, pay, and emoluments of a colonel; and two assistant medical purveyors, with the rank, pay, and emoluments of lieutenant-colonels, who shall give the same bonds which are or may be required of assistant-paymasters-general of like grade, and shall, when not acting as purveyors, be assignable to duty as surgeons by the President; fifty surgeons, with the rank, pay, and emoluments of majors; one hundred and fifty assistant-surgeons, with the rank, pay, and emoluments of lieutenants of cavalry for the first five years' service, and with the rank, pay,

and emoluments of captains of cavalry after five years' service; and four medical store-keepers, with the same compensation as is now provided by law; and all the original vacancies in the grade of assistant-surgeon shall be filled by selection by competitive examination; and the Secretary of War is hereby authorized to appoint from the enlisted men of the Army, or cause to be enlisted, as many hospital-stewards as the service may require, to be permanently attached to the Medical Department, under such regulations as the Secretary of War may prescribe. And the number of contract surgeons shall be limited to seventy-five on or before the 1st day of January in the year 1875; and thereafter no more than that number shall be employed.

"Section 5. That the Ordnance Department shall consist of one Chief of Ordnance, with the rank, pay, and emoluments of a brigadier-general; three colonels, four lieutenant-colonels, ten majors, twenty captains, sixteen first lieutenants; and all vacancies which may hereafter exist in the grade of first lieutenant in said Department shall be filled by transfer from the line of the Army: *Provided*, That no appointment or promotion in said Department shall hereafter be made until the officer or person so appointed or promoted shall have passed a satisfactory examination before a board of ordnance officers senior to himself."

It will be seen at a glance that no attention whatever has been paid to the memorial of the American Medical Association, and that two of the higher grades of the service have actually been cut down, there being only two lieutenant-colonels where there were formerly five, and fifty majors where there were sixty. The reduction in the first of these grades, it should be stated, however, is not quite so great as it appears, as one of the number has been promoted to a colonelcy. The only advance made by the bill, so far as we can see, is in throwing open the position of assistant-surgeon; and it is a question whether this is a real advance, since the opening of the doors is accompanied by the withdrawal of those inducements which affect most powerfully the best material.

As "example is better than precept," and as a personal illustration often brings the matter home to a reader, perhaps our friends Drs. Billings and Otis will not think we are using their names like a foot-ball if we state that the present bill delays their promotion about seven years,—*i.e.* they will have to serve about twenty years to become majors, and never can rise any higher.

Railing at the bill will, unfortunately, never change it, and the only true work of the present is to devise means to influence the next Congress. The past has shown that resolutions of Medical Societies are about as powerless in influencing legislation as a feather would be in sinking an iceberg. There is

one way in which, however, the profession could, if it would act unitedly, turn the next Congress topsy-turvy. Every member of that august body has his family physician, and is also well known by other doctors; now, if these medical men would as individuals make their best endeavors to obtain personal pledges from the Congressmen, the desired object would be achieved. The close, private, hand-to-hand grapple with a man offers the best and surest method of permanently altering his opinion. We shall never forget a scene in one of our legislative halls. A certain measure affecting the profession was, if possible, to be pushed through, and among our party was a veteran non-medical politician and lobbyist. The committee was to have a hearing before the assembled house in the evening, but our lobbyist insisted upon getting hold of the individual members previously, saying, "D—n this shooting into flocks! pick out your birds singly, and fetch them down one after another." The more we have seen of legislative bodies, the more we have been convinced of the wisdom of this advice.

Of course, since the law directs it, the vacancies among the assistant-surgeons will be filled. We understand that there are fifty-six of them, and that an examining board will convene at New York about the 1st of August, and also that another board will meet at San Francisco either simultaneously or or at a somewhat later date.

HOSPITAL SUNDAY has recently been tried in Boston, and a little over thirteen thousand dollars was subscribed during the day. In London, the result of this year's anniversary is stated to have been a little larger than the amount subscribed at the corresponding date last year. To July 1, £26,600 had been reported. We should very much like to see the plan tried here, but unless the support of the whole profession can be obtained it seems to us useless to expect any good. Very possibly the sectarian nature of many of our institutions would be a barrier.

DR. E. S. GAILLARD has started a new journal, entitled *The American Medical Weekly*. The *Northwestern Medical Journal* has been discontinued.

THE Council of the British Medical Association has decided in favor of a grant of two hundred pounds to be spent in original researches.

CORRESPONDENCE.

TO THE EDITOR OF THE PHILADELPHIA MEDICAL TIMES:

I SEE by your issue of July 11 that my friend Dr. Bernardy claims priority in the use of *chloral* in *puerperal convulsions*. I must dispute his claim. In October, 1871, I employed this remedy successfully for the relief of convulsions induced by excessive drinking. At the time I mentioned the fact to Dr. William F. Patterson, and suggested it as the remedy for puerperal convulsions.

On the 26th of October, 1871, Dr. Patterson summoned me to meet him in the case of Mrs. T., on Federal Street. He had, in pursuance of the suggestion as above, been employing the chloral, but in small doses, and I believe the article was of an inferior quality.

We agreed to procure a reliable supply from a good source, and increase the dose, giving it at intervals of one hour. So soon as she came under the influence of the chloral, the attacks ceased, and she rapidly convalesced.

Since that time, in a number of cases, both in consultation and in my own practice, I have continued to employ the chloral, and with the most complete success.

I publicly expressed my earnest belief in the virtues of this drug in cases of puerperal eclampsia on the occasion of my address on Obstetrics before the Medical Society of the State of Pennsylvania, at Easton, May, 1874.

Very respectfully,

W. B. ATKINSON, M.D.

PHILADELPHIA, July 13, 1874.

PROCEEDINGS OF SOCIETIES.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

A CONVERSATIONAL meeting was held Wednesday, April 22, 1874, at 8 o'clock P.M.

The PRESIDENT, DR. W. L. ATLEE, in the chair.

Dr. A. G. B. HINKLE read the account of a case of *hydrophobia*.

On the 4th of March, 1874, S. D., a car-spring maker, called at my office, stating that on the day previous, whilst working very hard and perspiring excessively, he had drunk largely of water. In the evening he felt greatly fatigued, and passed a restless, wakeful night. In the night he attempted to drink water, but found great difficulty in swallowing. On examination of his fauces I discovered slight local congestion of the parts, and, thinking the trouble might arise from it, I ordered him a saline purge; also twenty-grain doses of bromide of potassium every four hours. His pulse was then not more than 70 per minute; tongue slightly furred and whitish.

On the 5th I was summoned to see him. He had passed another sleepless night, and had attempted to drink water, but found it impossible to get it to his mouth, in consequence of the spasm that it excited; when he attempted to bathe his face he could not touch the water, from the same cause. Pulse about 80, and soft; tongue covered with a slightly brown-

ish fur; skin cool and somewhat livid, but dry; expression anxious; complained of pain in right arm from neck down to the finger-nails, and particularly of the right thumb. The temperature of right arm was higher than that of the left. He also had pain from back of neck extending to the pomum Adami, and a peculiar painful sensation in the region of the diaphragm and the scrobiculus cordis. The cathartic taken the previous day had not acted; the urine was scanty; there was frequent sighing; there was a sense of pressure upon the throat; the eyes were wild and sparkling at times; a retraction of the angles of the mouth simulated the sardonic grin; the face was at times suffused, then again somewhat livid. A current of cool air would produce spasmodic contraction of the muscles of face, pharynx, and respiratory organs generally.

I requested him to let me see him take a drink, and on pouring the fluid into the glass I observed that the noise it caused excited considerable spasm. The attempt to swallow was painful to witness, it causing him to rush to the door gasping for breath. He had taken but little nourishment during the past twenty-four hours, as that effort caused the same spasmodic symptoms as drinking.

I then cautiously inquired if he had ever been bitten by any animal, and learned that on the 30th of September, 1873, in attempting to catch a little dog that ran into the shop where he was working he had been bitten by it twice in the thumb of the right hand quite severely, but he had given no particular attention to the subject, the wound healing kindly in due time. What became of the dog we have not learned, as it escaped from its captors.

I then ordered a large enema of soapsuds and turpentine, which was given with some difficulty on account of the contraction of the sphincter ani muscles; a very slight fecal discharge followed. I then gave him one-third of a grain of sulphate of morphia hypodermically, to be followed in two hours by a suppository of two grains of the aqueous extract of opium. This had the effect of relieving him of the severe pain in the neck and arm to a great extent. I also painted the upper part of the spinal column with blistering collodion, which did not act.

Dr. William Welch saw him with me in the afternoon; the pulse was then about 86; he was suffering less pain, but his other symptoms were about the same. He had slept a little at short intervals.

In the evening Dr. Millick saw him with me; the pulse was about 90, and there was no further abatement of the symptoms. We gave another third of a grain of morphia hypodermically, and an enema of three ounces of *lac assafoetidae*, with half an ounce of tinct. digitalis.

On the morning of the 6th I found him no better, he having slept none at all; the pupils were somewhat dilated; the pulse 100. At the suggestion of Dr. Stetler we tried the effect of the inhalation of a mixture of four parts of ether to one of chloroform, with the view of relaxing the spasmodic condition. Of this he had scarcely taken half a dozen inhalations when he sprang from his resting-place and became very violent, rushing out of the door and down into the cellar, and requiring considerable effort to force him back to his former position. This stage of excitement continued during several hours, but gradually subsided by evening. During this stage he foamed greatly at the mouth, and at times grew very livid in the face and about the extremities; his pulse rose to 120.

In the evening Drs. R. S. Kenderdine, G. M. D. Peltz, Lewis Adler, and Rudrow, saw him with me. The pulse was feeble, but increased to 135; the skin cool and moist. He was more rational, and the spasms had almost subsided. I gave half a grain of morphia hypo-

dermically, and painted the spine again with blistering collodion. On the morning of the 7th he had slept none; the pulse was 140, the skin cool and shrunken, the expression sardonic, the face livid, the capillary circulation very feeble. We gave him one drop of croton oil, to be followed by two grains of calomel every two hours; and, as the former blistering had no effect, I again painted his spine with a fresh sample that I knew to be reliable, but with no effect whatever.

In the afternoon his pulse was 140 in the recumbent posture, and in the upright position so feeble that we could not count it; the purgatives had not acted; abdomen tumid; had three more spasms during the day, and finally almost complete hemiplegia of right side.

At 9½ in the evening the pulse was fluctuating very much, so that it could not be counted. There was a general relaxation of the whole system. He was quite rational at times, and swallowed beef-tea quite freely, and even asked for a chew of tobacco. I gave him a large enema without effect, and afterwards gave forty drops of Squill's liq. opii compos., which caused a brief slight drowsiness; about 11 P.M. a feeble return of spasm for a short time occurred, and he then gradually sank until his death, at 2 o'clock in the morning.

From the commencement of the attack to its final close about four days elapsed. No post-mortem could be obtained.

We believed the case to be hydrophobia, and directed our efforts for temporary relief to the best of our abilities, and were gratified that we were instrumental in relieving him to a great extent of the pain, and partially also of the spasmodic condition. The primary wound did not show any indications of opening.

Dr. A. FRICKE said he had presented to the Society, some years ago, a paper on hydrophobia published in the Transactions of the State Medical Society, in which several cases were related. The incubation in one of the cases was two years; the ordinary time was six weeks. How could the poison slumber such a length of time and then wake up? The other case was sent to the hospital. Wunderlich relates the case of a woman bitten in her clothing. Mending her dress the next day, through an abrasion she took the poison. He mentions a case in which there was an incubation of twenty-seven years.

Dr. O'HARA remarked that syphilis remains long in the system. He did not see how this case could be distinguished from brain-disease. He did not think the fear of water a symptom, as it belonged to other disorders. Dr. O'H. asked whether vesicles appeared under the tongue. Trousseau had pointed them out as prodromes. In cases of brain-disease, as localized meningitis, etc., there were symptoms analogous to those described as occurring during hydrophobia. An enema would throw them into spasms.

Dr. STETLER saw this case about thirty-six hours after its onset. There appeared to be a great deal of hyperæsthesia when cold water or currents of cold air came in contact with the skin. Properly or etymologically speaking, he could not pronounce it a case of hydrophobia at that period, for on taking up a tumbler of water immediately in front of the patient, and presenting it to his (Dr. S.'s) lips, the patient remained unmoved. We also resorted to the expedient of placing his hands in a basin of warm water, and, although he moved them about in the water freely, there was no emotion of an unpleasant character. Was it then hydrophobia?

Dr. S. saw a reported case of hydrophobia four years since, but which was an undoubted case of tetanus, according to the testimony of the three physicians in attendance. The man had thrust his hand down the throat of a heifer that subsequently died, but not of hydrophobia. The impression got out early that it was

hydrophobia of which the man died, and it was impossible to remove it. The case occurred in very warm weather. The patient, after returning from church in a state of perspiration, very imprudently lay down on the lawn, was soon seized with symptoms of opisthotonos, and died on the fifth day.

Dr. BLACKWOOD reported the case of a woman who was bitten six years ago, in Huntsville, Alabama, under his charge. A rabid dog entered the camp, and, before being killed, bit the wife of the drum-major, and two dogs. The first bitten was one of the dogs, next the woman, and finally the other dog. The wounds in the woman's hand were thoroughly cauterized with nitric acid, and she has not been troubled yet with hydrophobia. Both dogs died in ten days, with rabies.

Dr. KEYSER mentioned a case that he had seen some eight or nine years ago, of a boy bitten, in which the wound was immediately burnt out with a lighted cigar by some one present, and, about an hour after, the wound was well cauterized with nitric acid. Never heard of his having hydrophobia afterwards.

Dr. ESHLEMAN cited the case of a relative bitten by a pet dog. The wound was excised and cauterized shortly after the injury. During sixteen years that he survived, no symptoms of the disease arose. The dog was pronounced rabid by a physician, and killed.

Dr. WELCH remarked that, through the courtesy of Dr. Hinkle, he had seen and examined the case related to-night, and, although he had never before seen a case of hydrophobia, believed such to have been the nature of the disease in this instance, since *dread of water* was the most prominent feature; that is to say, that every attempt to drink or handle fluids brought about a peculiar train of symptoms, most prominent among which were spasmodic action of the diaphragm, giving rise to hurried and jerking inspirations, and severe constriction about the throat, rendering deglutition extremely difficult. Two visits were made to the patient, one on the second and the other on the fourth day of the disease. At the first visit the patient was still conscious; the pulse was rapid and feeble; the complexion was sallow; there was occasionally slight twitching of some of the muscles of the face; there was general weakness; slight pain and numbness were complained of in the right arm (the thumb on this side had been bitten); and the gait of the patient was unsteady or staggering. But it was not until water was poured from a pitcher into a tumbler that the distinguishing features of the disease became manifest. This act immediately excited the peculiar train of spasmodic symptoms already referred to, all of which were aggravated by an attempt to swallow. When asked to take a drink, he reached for the tumbler with a tremulous hand; his respiration became at once exceedingly spasmodic, his face grew turgid and livid, and his eyeballs appeared prominent. After seizing the tumbler it seemed to require considerable effort to bring it to his lips, and when he had succeeded he made a determined effort to drink, but was able to swallow only very little of its contents. Under the excitement brought about by this futile attempt to swallow, he quickly set the tumbler down, and ran, in a staggering gait, to the door leading to the street, and, after standing there a few seconds, returned, stating that this act seemed necessary in order to get his breath. He soon became comparatively calm, when a basin of water was brought, and he was asked to immerse his hands; this also gave rise to a disturbance of the respiratory act, but to a less marked degree than the attempt to drink. The effect somewhat resembled that produced by stepping into a cold bath. The "hydrophobic slaver," spoken of by authors, was not observed. There was, however, a tenacious quality about the saliva, as was seen by the lips sticking together when parted.

At the second visit the patient had grown much weaker; he was unable to walk; the skin was congested, and of a livid hue; the pulse was very feeble, and so rapid that it was impossible to count it; there was delirium; partial paralysis of motion was observed on the right side, and sardonic smiles played over the countenance. Death ensued in about ten hours from this visit.

Dr. PAGE called the attention of Dr. Smith to a case which occurred in the Pennsylvania Hospital some years since, and said he knew one case in which the patient was smothered to death by his attendants.

Dr. H. H. SMITH, in reply to Dr. Page, stated that his recollection of the case referred to in the Pennsylvania Hospital, some twenty-five years ago, was that it was hydrophobia; being attended by violent spasms if a current of air blew on the patient, or water was poured out in his hearing, or an attempt made at drinking. There was also a collection of viscid saliva about the mouth and fauces, with constant efforts to hawk and spit. These symptoms followed the bite of a dog some time before. There was, however, a diversity of opinion in the diagnosis, some of the surgeons regarding it as a case of tetanus.

In reference to the bite of cats, Dr. Smith remarked that in one instance, in a mill in Delaware County, a cat, supposed to be mad, had bitten several persons. He saw three of these and cauterized the wounds, but never heard of hydrophobia attacking any of those bitten.

MEDICAL SOCIETY OF THE COUNTY OF ALBANY, NEW YORK.

SEMI-MONTHLY MEETING, MAY 13, 1874.

Dr. WM. H. CRAIG, President *pro tem.*, in the chair.

Dr. L. T. MORRILL reported the following interesting case of *pelvic cellulitis resulting in pelvic abscess*. Mrs. G., æt. 39, had had ten children and four miscarriages. About eighteen months before her death she was delivered at full term of a strong and healthy male child. For one month afterwards she suffered with severe pain over the pelvic region. Dr. Morrill at this time was consulted, and found her complaining with severe pain over the abdomen, which was tympanitic. Pulse 110. It was considered a case of peritonitis. Two weeks later her pulse had diminished to 90 per minute, and her abdomen was not so much distended. She had now a profuse diarrhœa. At the end of the next week the peritonitis had almost entirely subsided, excepting over the region of the left ovary, where the pain was intense, and the only relief she could obtain was from the use of hypodermic injections of morphia. Being naturally robust, her strength held out, and in the course of three or four months she was able to go about, and commence the use of the sewing-machine.

She now seemed to improve rapidly; when one night her husband came home intoxicated, and commenced abusing her, pulling her out of bed and kicking her several times over the abdomen. The next morning she had much pain in the abdomen, which was bruised and swollen. Fomentations of warm water and anodynes were prescribed to procure relief. She survived eight months.

Four months before death, on examination of the abdomen, a fluctuating tumor, the size of a goose-egg, could be plainly felt, which gave intense pain when touched. On examining her per vagina, the tumor could be felt projecting to the left of the cervix uteri, or occupying the space where the normal cervix should be found. During the examination the abscess broke, and pus continued to discharge through the vagina.

about one-half a pint in quantity. This seemed to diminish the pain. The odor from the discharge was extremely fetid, to correct which she used a vaginal wash containing carbolic acid. By the use of tonics and a supporting treatment, she seemed to improve for two weeks, when suddenly the pain, heat, and swelling returned, and for twenty days the abscess filled and enlarged until it discharged the second time. With an intermission of three weeks each time, it gathered and broke five times. During the last month she was much debilitated, and seemed to die from exhaustion.

Post-mortem, twelve hours after death. Rigor mortis marked. Body much emaciated.

Thorax.—Right lung in a healthy condition, with a few slight adhesions to the costal pleura, probably of long duration. Left lung was firmly adherent, and in the upper portion was a cavity which contained two ounces of pus. Heart small, walls firm, valves normal. Peritoneum and its layers presented some traces of inflammation. In the left inguinal region the folds of the peritoneum were strongly adherent to the parietes of the pelvis and intestines. Just behind the left broad ligament, and under the pelvic folds of the peritoneum, surrounding the left ovary, were found the walls of an abscess, a part of its contents having made its way downward back of the uterus into Douglas's *cul-de-sac*, and escaping into the vagina. The sac probably contained about twelve ounces. There were two distinct openings into the posterior walls of the vagina. The fimbriated extremity of the Fallopian tube of the left side was firmly included in the peritoneal adhesions. The right broad ligament, appendages, and attachments presented a normal appearance. The uterus was normal in size. On laying it open, well-marked traces of endometritis were found.

The liver was in a state of fatty degeneration. Spleen firm, and capsule covered with a thick, white fibrous deposit. Kidneys and other organs were healthy.

Dr. JAMES S. BAILEY mentioned the following case of *abscess in broad ligament, rupturing, causing peritonitis and death*, which had recently come under his observation. A stout German, primipara, who had been delivered by a midwife of a healthy male child twelve days before he was called. He could not learn that during delivery there was anything peculiar, excepting that labor was protracted, and that she had complained of a burning, smarting pain in the right iliac region during her confinement.

When Dr. Bailey saw her she was in a moribund condition, and died within twenty-four hours.

It then came to his knowledge that the father of the child, the man with whom she was living, was not married to her, and, although she had respectable friends and relatives living in the city, they were not acquainted with the circumstance; through this man he met with strong and determined opposition against making an autopsy, and it was not until he threatened to call a coroner that consent was obtained. On section, a high state of peritonitis was found; the intestines had become agglutinated and bound down by a thick coating of plastic lymph, with more or less free pus floating in the abdominal cavity.

In searching for the cause, it was found that an abscess had been ruptured, located within the folds of the right broad ligament of the uterus, which caused peritonitis and death.

Dr. B. remarked that he had noticed in Dr. Morrill's report that the abscess was located on the left side. He had also noticed among fourteen cases collected by Dr. T. Gaillard Thomas from different authorities, that when the broad ligament was the seat of purulent collections the left side was invariably attacked. In his case it was on the opposite side.

Dr. JAMES S. BAILEY also exhibited a *biliary cal-*

culus, egg-shaped, weighing five drachms lacking six grains (or two hundred and ninety-four grains), which he had recently taken, at an autopsy, from an old lady 76 years of age. Its presence had not been suspected by the attending physician, although in her lifetime it had occasioned considerable inconvenience. It entirely filled and distended the gall-bladder, leaving an impress of the crystals contained on one end of the stone. Its presence had at some time excited considerable inflammation, as the adjacent edge of the liver was drawn down and united by adhesive inflammation, and the gall-bladder was also strongly united to the duodenum. The ductus choledochus communis was elongated and dilated.

Dr. ALBERT VANDERVEER said that he wished to call the attention of the members of the Society to a class of *strictures of the male urethra* which have been too much overlooked. We can say the same here as in many other branches of surgery, that our methods of examination, instruments recently invented, etc., have enabled us to arrive at a more correct diagnosis than we were formerly in the habit of reaching.

Most of us have been taught that to have a case of stricture of the urethra we must have such diminution or contraction in the calibre of the canal that the attention of the patient himself is first attracted to his condition.

He is first to notice that his stream of urine is growing smaller, that it requires a longer time for him to empty his bladder, that after a short time he finds he is compelled to make quite an effort, that the force exerted is so great as to give him much anxiety. He comes to realize the fact, without consulting a physician, that he has a stricture, and a careful examination only goes to confirm his opinion.

Now, in contrast to some of the marked symptoms just noticed, we have a patient coming to us stating that some time within one, two, three, or five years, or longer, he has had an attack of gonorrhœa. He may be of the opinion that at the time he believed himself cured, or he may state that the doctor who attended him did not treat his case properly, and that ever since he has had an annoying gleet.

He is positive that he is passing a full stream of urine, will perhaps state that he does not have to get up at night to urinate, and will, when it is suggested, scout at the idea of his having a stricture.

He is now a young man of correct habits, and desirous of entering the marital relation, or he may have passed on to middle life, and now, after some excess or great anxiety, notices a condition that makes him anxious to know whether there is not some danger of his old disease returning.

Whatever is his condition in life, his case demands a most careful consideration. All are familiar with a class of cases that suffer from what is called gleet, and can readily call to mind instances where by some happy combination of remedies, as an injection or otherwise, the discharge has been relieved.

Other cases again, apparently of like character, have taxed our skill to relieve, and, while anxious to continue our exertions, we notice that our patient discontinues his visits to us and has consulted another physician, perhaps in like manner to discard him after a short trial of his treatment. Thus too frequently does the patient travel year after year from one physician to another.

As an illustration, Dr. Vanderveer presented the history of the following case. F. C., merchant, aged 26, temperate, had his first and only attack of gonorrhœa five years ago. The discharge was profuse and very irritating. He was under treatment a year, and then believed himself cured. Three months more elapsed, and, while enduring great fatigue, he noticed a slight discharge from the urethra on rising in the morning,

and a desire to empty the bladder occasionally during the night. He consulted many physicians, but only one had examined the urethra, and he only with a No. 10 elastic bougie. This passed into the bladder with comparative ease. It was believed that he had no stricture, and he used injections of lead, zinc, nitrate of silver, and various other astringents, also has taken medicine internally most of the time during the past four years. Dr. Vanderveer first saw this patient March 9, 1874. He appeared strong, and said he had nothing to worry about excepting this unpleasant gleet discharge, which is very scanty in quantity, but he is anxious to get married, and fears a return of his clap. Is sure that he is passing as large a stream of urine as ever, but admits that it requires more force and a somewhat longer time than usual to empty his bladder. An examination with a No. 8 bulbous-pointed bougie brought a drop or two of gleet discharge from near the meatus, but on being reintroduced it passed the entire length of the urethra, and was removed without detecting a stricture.

A No. 11 entered the meatus, but met with a decided obstruction one-third of an inch back. This was passed after some effort, and then on into the bladder. On removing it, no contraction could be detected excepting near the meatus as mentioned, and here a well-defined stricture, one of large calibre, can be diagnosed. The instrument was held by the stricture with sufficient firmness to hold the penis erect.

The patient was then convinced that he had a stricture, and was willing to submit to any treatment thought best to relieve him. The stricture and meatus were freely incised with Gouley's meatotome, and a No. 16 steel sound passed into the bladder; but little hemorrhage followed. He was taught and told to pass a large-sized black elastic olive-pointed bougie two and three times a week, and to report again. No internal treatment ordered.

He returned in three weeks, and said that the discharge had ceased, and that his mind was greatly relieved concerning his disease.

The largest-sized bulbous bougie failed to detect any remains of the stricture. He was ordered to continue the use of the elastic bougie occasionally.

If we had attempted to make out a diagnosis of this man's case according to the rules presented in many of the text-books of the present day, we should have failed. Sir Henry Thompson, with others, tells us that if a No. 8, 10, or 12 elastic bougie or steel sound can be passed the patient has no stricture. It is very evident that this cannot be the case, and also that we are not safe in our diagnosis when a gleet discharge is present unless we have made a thorough use of the so-called bulbous bougie. In searching after the location of a stricture that may be present, one point in our diagnosis of strictures of large calibre we are to remember: that every urethra is not of the same size.

An illustration will explain. A. S., treated for light stricture and discharged as recovered, May 1, 1873. A No. 16 steel sound had passed readily. He returned again in January, 1874, saying that, while he passed a good stream, and was not able to detect any gleet discharge, yet of late when he has urinated and about to return his penis he has noticed an unexpected dropping of urine, which from its soiling his garments has become very annoying. On examination, a No. 16 steel sound passes into his bladder, causing a little pain at the meatus.

By examining this case somewhat more carefully we find there is some trouble in introducing the large-sized bulbous bougie; the meatus is incised, and then we detect in the spongy portion of his urethra four well-defined strictures of large calibre, one-half inch from each other, all sufficiently well marked to retain a drop or more of urine. In the treatment of this case we

first tried Otis's dilating urethrotome, but succeeded best with Gouley's dilating urethrotome, and after a short time had the satisfaction of seeing the patient entirely relieved of all his troublesome symptoms,—the urethra admitting the passage of No. 17 and 18 steel sounds, and the largest-sized bulbous bougie being unable to detect any contraction of the canal.

In examinations of cases of gleet we should always bear in mind that the stricture of large calibre may become the tight, impenetrable one that the former is, treated with far better results, easier, and with less loss of life than the latter.

Dr. Vanderveer believed that all cases of gleet resolved themselves into two classes,—those complicated with stricture either of large or small calibre, and those where we have the urethra presenting points of ulceration after a severe attack of urethritis, and which, if neglected, ultimately lead to stricture.

In order not to detain the Society too long, Dr. Vanderveer only proposed to present a few cases to show the good resulting from gradual dilatation, a method always at hand and easy of application, especially if it be but a short time since the acute urethritis has occurred.

Case III.—September 1, 1872, G. J., small in stature, æt. 23, habits temperate, first attack of gonorrhœa two and a half years ago, and very severe, but recovering in three months; was treated with copaiba only. The second attack occurred eighteen months thereafter, but was not so severe. The treatment was the same as the first. A constant discharge has continued since. A No. 8 bulbous-pointed bougie detects a stricture one-half inch from meatus. Gradual dilatation with elastic bougie continued for three months, and finally used No. 15 steel sound. Internally used tinct. ferri with cantharides. Discharged August, 1873, entirely cured, with no relapse up to the present time.

Case IV.—April 10, 1873, W. J., æt. 22, temperate habits, has had two attacks of gonorrhœa, the last a year ago, since which time there has been a constant gleet discharge. Twice after severe exposure he has been obliged to resort to the use of the catheter to draw off his urine, which was introduced at such times with little trouble. Examination with a bulbous bougie reveals a slight stricture just back of the fossa navicularis; the remaining portion of the urethra appears healthy. Nos. 13 and 15 steel sounds were passed twice a week for a month, when the discharge entirely ceased, and has not returned up to this date,—August 15, 1873. His general health being good, no internal treatment was applied.

There are cases existing with points of ulceration in the urethra which we sometimes may have the good luck to locate correctly and treat by means of injections, but which can be more certainly and correctly located by means of the endoscope,—an instrument which should come into general use. The following affords a good example: D. D., æt. 40, intemperate, exposed to the vicissitudes of atmosphere day and night; first attack of gonorrhœa eighteen years ago, which was treated with copaiba, injections, etc. He was four months in recovering. After this, after exposure to cold the stream of urine became smaller, followed for a few days by a gleet discharge. Second attack two years ago, which was very severe, and attended with great pain and scalding; treated with copaiba and injections; was three months in recovering. The stream of urine became smaller, but there was no retention; was obliged to empty his bladder during the night. Third attack, four months ago, was very painful; the swelling and scalding were very aggravated; occasionally passed blood with the urine. The attack yielded to the use of copaiba and injections, but he could subsequently only after frequent attempts pass a

small stream of urine. Examination showed the urethra to be in a state of ulceration for five inches, and to be uniformly contracted and roughened. The introduction of a No. 2 elastic olive-pointed bougie was attended with considerable pain, and caused the parts to bleed. Tr. ferri and cantharides were taken internally. The occasional use of bougies up to No. 8 leaves the patient in a very comfortable condition. Discharge is quite scant. Introduction of No. 8 bougie causes no pain. The introduction of a larger-sized bougie causes much pain. He will not permit further treatment with urethrotome or divulsor. Eight months after treatment was commenced remains comfortable; uses No. 8 bougie occasionally: refuses further treatment.

Dr. T. D. CROTHERS read an interesting paper on "Impure Milk a Source of Disease," which did not, however, contain much at once of general interest and actually novel, and which we therefore omit from want of space, excepting the following:

A gentleman in this city bought a young cow to have pure milk for his child. The process of milking was, from ignorance, attended with much excitement and brutality, and the child was seized with brain fever, and never entirely recovered,—the direct result of feeding this poisonous milk, made so by the excitement of milking. A case was also related by him where a brutal, drunken dairyman supplied four families with milk. Those who used the most milk suffered all the season from gastro-intestinal irritation and a low tone of physical and mental health, due, without doubt, to the changed and poisonous condition of the milk from excitement.

Dr. J. B. STONEHOUSE spoke of a case reported in the *Edinburgh Medical Journal* for January, 1868, by Dr. Taylor, where scarlet fever prevailed in a dairy district and was propagated through the milk to the consumers. It was ascertained that patients and nurses, after having passed through the stage of desquamation, milked the cows, and it was supposed that the scales from the arms or from their dresses were shaken off in the milk, and thereby contaminated it.

In London, in a certain district it was observed that the milk tasted of creasote; the milk was stopped, and the circumstance reported to the authorities. It was ascertained that certain drains had been stopped up, and were cleaned out and disinfected with creasote; the creasote was absorbed by the milk from the air. Reference was also made to the paper on this subject in the *London Practitioner* of last year, when typhoid fever was communicated by the milk-vessels being washed with water contaminated with sewerage-water and dried in the sun without wiping. He also was of the opinion that milk proved unwholesome by absorbing noxious gases.

Dr. HALE could not see any propriety in feeding children on the milk from a certain cow. He was of the opinion that the product of a dairy where the milk from many cows was mixed would be more healthful to children. In cases of alleged milk-poisoning he believed more depended upon the lack of cleanliness in the nursing-bottle than on the impurity of the milk.

GLEANINGS FROM OUR EXCHANGES.

EXCISION OF THE ANTERIOR TARSUS AND BASE OF THE METATARSUS.—A NEW OPERATION (*The Edinburgh Medical Journal*, May, 1874).—Dr. P. H. Watson reports the case of a lad, æt. 19, who suffered from disease of the anterior portion of the tarsus. It was spontaneous in its origin, subacute in its progress, involving the articulations chiefly upon the inner side

of the foot between the cuneiform bones and metatarsal bones. The pain was such that he was unable to work or walk. Under rest, blistering, and constitutional treatment he improved until the plaster of Paris could be applied, but after the lapse of a few months the original symptoms returned with increased severity. No collective abscess had formed in the soft parts, but there seemed no reasonable doubt that suppuration had already commenced within the bones and joints involved. To amputate the foot seemed too severe a measure to be justifiable under the circumstances, and as it was obvious that all the disease was confined between the base of the metatarsus in front and the astragalus and os calcis behind, and that the excision of the scaphoid, cuboid, and cuneiform bones and bases of the metatarsal bones would secure the fulfilment of every requisite for sound recovery, the following operation was performed. After the application of the tourniquet to the lower part of the thigh, incisions between three and four inches in length were made in the outer and inner sides of the foot, that upon the outer side extending from the centre of the outer margin of the plantar surface of the os calcis as far as the middle of the metatarsal bone of the little toe, that upon the inner side from the neck of the astragalus to the middle of the re-established bone of the great toe. The soft parts were then carefully dissected off both surfaces and sides of the tarsus until the whole extent of osseous tissue to be removed was deprived of its soft coverings. A curved probe-pointed bistoury inserted between the soft parts and bones was then carried across the line of articulation between the astragalus and scaphoid and os calcis and cuboid bones, first upon the dorsal and then upon the plantar surface, so as to open up these joints. A key-hole saw was now introduced between the plantar soft parts and the shafts of the metatarsal bones, which were then cut through, one handle of a pair of bone-forceps being inserted between the metatarsus and the dorsal soft parts to protect the latter from injury by the teeth of the saw cutting from below upwards. After the operation the entire wound was plugged firmly with pledgets of lint closely crowded together. This dressing was retained for forty-eight hours, and subsequently the wound was filled from day to day with pads of lint, with a view of securing consolidation from all surfaces equally, and of preventing the bagging of matter.

The result in this and four other similar cases was entirely favorable,—the patient's walk having none of the stumping gait of an amputation.

OLLIER AND OTHERS ON RHINOPLASTY BY A NEW METHOD.—In the *Union Médicale* of April 25, 1874, is the account of a discussion at the Surgical Society of Paris on rhinoplasty, à propos of some cases by M. Ollier, in which he had attempted the restoration of the nose by a new proceeding. This proceeding was applied to cases in which the remains of the nose were, as M. Ollier expresses it, "sucked into the nasal fossæ." It consisted in dissecting a flap from the forehead, comprising both superficial parts and periosteum, and reversing it so as to present its cutaneous surface towards the nasal fossa, where it was expected afterwards to take on the characters of mucous membrane, while the bleeding surface was covered over by a flap dissected off the remains of the collapsed nose. The result was said by M. Ollier to be satisfactory, not only to himself, but to his patients, whom he regarded as still better judges of their own improvement; but some very lively discussion seems to have ensued on this point, some of the surgeons present being by no means pleased with M. Ollier's results, and not at all favorable to any operations of this kind. One of the debaters quoted the case of a patient who, from despair at the disgust produced by his mutila-

tion, had resolved to kill himself, but was weaned from his purpose by the results of the operation. This was met by another speaker, who said that he had another patient, who had thought also of killing himself, and was more than ever confirmed in his resolution when he saw the result of the operation on the other man. This need not be taken seriously; but it seemed agreed on all hands that the effects of such plastic operations are usually only temporary, and that in a year or two the newly-formed nose will most likely wither away. The operation by superimposed flaps seems to have been practised by other surgeons as well as by M. Ollier, and to be regarded as a very efficient proceeding.—*London Medical Record*.

PSEUDO-HYPERTROPHIC MUSCULAR PARALYSIS (*The Lancet*, June 6, 1874).—Drs. Clarke and Genners report the case of a boy who died, aged fourteen, from general muscular atrophy. The muscles of the calf had been from an early age, and until within two or three years of his death, considerably larger than natural. Difficulty in locomotion, due to muscular weakness, had been noticed from the time when he commenced to walk, at three years old, and had increased until he ceased to walk at eight, and to stand at ten. During the last three years of his life the calves lessened in size to below the normal, and the muscles of the thighs and arms became atrophied. At the time of his death, from pneumonia, he could not move the hip, knee, or shoulder-joints; he could move the ankle- and elbow-joints a little, and the fingers well. After death the muscles showed in various degrees the characteristic changes of Duchenne's disease. The gastrocnemii looked like lumps of fat, and under the microscope consisted of fat-cells, among which still ran some muscular fibres, accompanied by a good deal of connective tissue. Very few fibres except those greatly reduced in width, presented any granular or fatty degeneration. The brain and medulla oblongata and meninges of the cord were healthy; the spinal cord itself presented various changes throughout the cervical, dorsal, and lumbar regions. The most important was disintegration of the gray substance of the anterior, lower, and central portions of each lateral half. These changes were much greater than any previously found.

LACTATION LATE IN LIFE (*Atlanta Med. and Surg. Journal*, July, 1874).—Dr. T. S. Hopkins reports two cases of the return of the functions of the mammary glands after a cessation of seventeen and eighteen years. Both women suckled their grandchildren, one of them being over sixty years of age at the time.

POPLITEAL ANEURISM CURED BY FORCIBLE FLEXION (*The Lancet*, May 30, 1874).—Mr. Benfield reports the case of a man, æt. 38, of good general health, who was troubled with a small pulsating tumor in the left popliteal space. A distinct bruit was heard on applying the stethoscope, and firm pressure on the artery above the tumor arrested at once both the bruit and the pulsation. Treatment by flexion was resolved upon.

A flannel roller was applied to the leg, which was now flexed upon the thigh, and the latter upon the abdomen. The leg and thigh were firmly bandaged together so as to maintain forcible flexion, and heavy sand-bags were also employed to keep the patient from rolling out of position. This procedure occasioned very great pain, and a quarter of a grain of morphia was given subcutaneously for its relief. About six hours from commencement of flexion the patient could bear the pain no longer, and the bandage was removed and the leg gently straightened. No pulsation or bruit was now discernible. Patient complained of being chilly, and the foot of the affected limb was decidedly colder than its fellow. The limb was encased in cotton-wool,

a pad of lint placed in the popliteal space, and a flannel bandage applied. It was then placed straight on a pillow.

The aneurism was now practically cured, but for the sake of safety the pad and bandage, together with rest in bed, were maintained for ten days. The man was then allowed to get up and take exercise, which occasioned no pain or inconvenience. He was thus kept under observation for about three weeks, when he was discharged cured.

MUSCULAR SPASMS AFTER EXCISION OF THE KNEE-JOINT (*The Lancet*, May 30, 1874).—Mr. Gay reports a case in which excision of the knee-joint was performed as a consequence of long-standing strumous disease. The operation was followed by entire exemption from pain, with promise of immediate union and rapid recovery. Six days afterwards, however, spasmodic twitchings, which had previously been a distressing symptom, returned with greater severity than before the operation, and became so incessant, distressing, and uncontrollable, notwithstanding remedies of all kinds, that amputation was performed. This was followed by complete recovery. No cause for the spasms could be discovered. The nerves were all healthy, and there was no apparent impaction of the soft parts between the bones. Mr. Gay considers the case unique.

MORPHIA IN PUERPERAL AND URÆMIC CONVULSIONS.—Prof. Loomis recently published an article in the *N. Y. Medical Record* relating a number of cases of uræmic convulsions healed by hypodermic injection of morphia and the internal administration of infusion of digitalis, the results being favorable in the majority of cases. If opium is admissible in the treatment of uræmic convulsions due to organic disease of the kidneys, it is none the less so in the treatment of the convulsions of parturition, which are due to an active congestion of the same organs, caused by pressure of the gravid uterus. The nerve-centres are irritated by the same poison in both instances: therefore the same remedies should be applied.

Dr. G. O. Morrison-Fiset relates a case (*New York Medical Record*, July 1, 1874) of puerperal convulsions treated by hypodermic injections of Magendie's solution of morphia, with a successful result.

Dr. A. M. Dam reports (*The American Medical Journal*, July, 1874) five cases of uræmic convulsions following scarlatina, and one case occurring in a woman, æt. 30, in the seventh month of gestation. They were all treated with morphia administered internally, and all recovered.

THE USE OF LARGE ENEMATA (*The London Medical Record*, May 6, 1874).—The practical results of the recent discussion in the German medical papers on the use of large enemata seem to be as follows:

1. Enemata, if sufficiently copious, will reach the small intestine, the ileo-cæcal valve notwithstanding, provided there be sufficient propelling force, whether that be gained by a long column of fluid in the apparatus (as in the use of irrigators), or by the patient's position, with the pelvis elevated, favoring the descent of the fluid, or by repeated action of the injecting instrument.

2. Experiments have shown that it is neither necessary to use complex apparatus, nor to put the patient into awkward and perhaps dangerous positions; since from three to five feet of pipe, with a funnel at one end and a suitable nozzle at the other, is all the apparatus we need; and the patient simply lies upon the back, the only pressure required being that of the column of fluid.

The real pressure we have to overcome is that of the patient's muscles,—aided in some cases by tense gases

in the bowel; for if any one will insert a tube into the rectum before the injection has come away, he will see the fluid come out in jets or sprits when the patients strain, and less markedly so at every descent of the diaphragm.

3. The safety and efficiency, or the benign action, of large enemata of water, gruel, and the like, are very striking; but we are strongly inclined, however, to believe that a very small quantity of soap, or of some neutral salt, is even less irritating to the mucous membrane than pure water alone.

To sum up all, large injections do reach the whole length of the large intestine, and beyond it; they are safe and speedy remedies for fecal accumulations, for some forms of intestinal obstruction (notably intussusception) and internal herniæ; for the treatment of intestinal ulcers, of hemorrhage from the bowels, and diarrhœa; for worms, especially oxyurides, and their congeners; as a means of stimulating and increasing the secretion of bile, and of introducing into the small intestine nutritious matters in a state easily susceptible of absorption.

A VERY active preparation of ergot, which is particularly adapted for subcutaneous injection, is suggested by Dr. Wernich, of Berlin (*American Journal of Pharmacy*, July 1, 1874), who proposes to exhaust the ergot with ether, strong alcohol, and finally with water; the infusion is then dialyzed through parchment-paper, and the solution evaporated; this extract, after acidulation with sulphuric acid, was mostly soluble in alcohol, and when again carefully neutralized by soda, yielded to weak alcohol all its active properties. Subcutaneously injected, the author obtained good results promptly, and the inconveniences attending the hypodermic use were slight and disappeared rapidly.—*Apothekerzeitung*, 1874, No. 17.

CHLOROFORM IN STRYCHNINE-POISONING (*The New York Medical Record*, July 1, 1874).—A man took five grains of strychnine with suicidal intent. He was given twenty grains of sulphate of zinc, which produced vomiting. Convulsions had occurred repeatedly, however, and he was seized with one of tetanic form at the time of coming under observation. Every muscle was rigid, and tetanus was complete. Opisthotonos, irregularity of the pulse, varying from 120 to 140 in the minute, with all the accompanying symptoms, were noticeable.

He was immediately placed under the influence of chloroform. The convulsions ceased from the commencement of the anæsthesia, under which the patient was fully kept for three hours. The chloroform was then removed, but the patient did not awake until six hours afterwards,—a case of recovery.

CHLORAL IN CANCER (*New York Medical Record*).—At a recent meeting of the Société Thérapeutique, the efficacy of chloral in cancer was pointed out by Dr. C. Paul, who had used it in the shape of suppositories containing fifteen grains. Introduced into the vagina, they had produced sleep during the whole night, in cases where considerable doses of morphia had no anodyne effect, while the nature of the secretions, and especially their fetor, were favorably modified. Dr. Martineau mentioned a case of recurring cancer of the breast, which had almost reached the thoracic walls and the lung. Pledgets of lint, steeped in a solution of chloral, were introduced. Three days after, the surface had assumed a healthy hue and was granulating kindly, the fetor had vanished, and the hemorrhage stopped. Cancer of the uterus had likewise improved, so far as the pain and fetor were concerned, under similar treatment.

STRUCTURE OF NERVES.—As the result of an elaborate investigation into the structure of nerve-fibres, Dr. H. D. Schmidt comes to the following conclusions (*London Monthly Microscopical Journal*, May, 1874):

"In finally summing up the results of my researches regarding the structure of the *double-bordered* nerve-fibre, this will be found to consist of the following parts: 1, of the true nerve-fibre, the so-called *axis-cylinder*, consisting of a bundle of *granular fibrils*, enclosed within a distinct sheath of their own; 2, of a semi-liquid substance, the *medullary layer*, surrounding the axis-cylinder; 3, of the *fibrillous layer*, consisting of very fine, delicate, and smooth fibrils, and surrounding the medullary layer; and, 4, of the *tubular membrane*, or *external sheath*, a thin, structureless, and elastic membrane, enclosing all the other parts. Whether, now, the thirdly-named part really exists in the living nerve-fibre, or whether it is only produced by coagulation, it must be decided by other, more accurate histological researches than those hitherto made."

APHTHOUS STOMATITIS COMMUNICATED TO MAN THROUGH THE MILK OF A COW AFFECTED WITH THE SAME DISEASE (*New York Medical Journal*, July, 1874).—A man partook freely of milk at a period when an epidemic of aphthous stomatitis raged among the horned cattle of the country. The symptoms commenced in less than half an hour after the ingestion of the milk. They consisted of vertigo, tingling in the ears, feebleness, afterwards delirium and hallucinations. On the second day, vomiting and diarrhœa with abdominal pains set in, which promptly yielded to treatment by opium and subnitrate of bismuth. The fever, however, was not broken, and on the third day stomatitis appeared, with pytalism, and the development of aphthæ on the inner surface of the lips and cheeks, on the palate, and the inferior surface and borders of the tongue. At the same time, there appeared a phlyctenular eruption on the hands, feet, perineum, and scrotum. The nervous disturbances, delirium, and insomnia were combated by opium, given in doses of fifteen centigrammes per diem, and the stomatitis by gargles of chlorate of potassium. At the end of fifteen days the patient recovered.

OAT-MEAL FARINA AS A FOOD FOR INFANTS.—MM. Beaumetz and Hardy recommend very highly the use of oat-meal farina in the feeding of young children. According to these gentlemen, this farina resembles human milk most closely in its plastic and respiratory elements, and contains, in addition, iron and phosphate of lime. It has, besides, the property of preventing or arresting the diarrhœa which so frequently occurs in young children. Some infants of four to eleven months, who were fed upon this farina, were found to grow equally well with those who were nourished by the milk of a good nurse.

EXTRAORDINARY ACTION OF NITRITE OF AMYL (*New York Medical Journal*, July, 1874).—Dr. E. B. Janeway reports a case of cerebral anæmia with failure of the heart's action from pericarditis, where the patient was entirely unconscious, pupils dilated, conjunctiva insensible to touch, no pulse at wrist, breathing spasmodic. Inhalations of five drops of nitrite of amyl were commenced and cautiously increased. After the use of twenty drops the pupils contracted, the conjunctiva responded to the touch, and the pulse returned at the wrist. Consciousness returned, and he asked questions. The inhalations were suspended, and a half-ounce of brandy administered. In fifteen minutes another attack occurred, in which he died.

DETECTION OF ALCOHOL IN ORGANIC FLUIDS.—It is generally difficult to detect alcohol in organic fluids, on

account of the small quantity of liquid usually available, and the absence of a special reactive. M. Berthelot has discovered a very valuable reaction. When placed in presence of water, cold or tepid, benzoic chloride ($C_{14}H_5ClO_2$) decomposes very slowly. But if alcohol is added, benzoic ether is immediately formed, and precipitates the chloride in excess. The presence of the ether becomes manifest when a few drops of the liquid are treated with a solution of caustic potash; the chloride alone is dissolved, and the ether remains untouched. This reaction is very marked with a liquid containing 1 per cent. of alcohol, and permits the chemist to dispense with distillation.—*Tribune Médicale*.

LATENT PEPSIN (*The Druggist's Circular and Chemical Gazette*, July, 1874).—George W. C. Phillips objects to the theory that all wines and elixirs of pepsin, necessarily composed of alcohol, contain no pepsin at all, which theory was based on the fact that certain wines of pepsin when digested with coagulated albumen, at a temperature approximating that of the human stomach, have no solvent effect upon it. He has tested this matter experimentally, and draws the following conclusions: That while a carefully made wine of pepsin, not containing over ten per cent. of alcohol, may and does contain pepsin, it exists in a latent state, and that when diluted with the juices of the stomach, at the normal temperature of that organ, it regains its activity and will perform its digestive functions.

MISCELLANY.

THE following is part of a parody which appeared in *Punch* upon Mrs. Hemans's "Homes of England."

"The cottage homes of England,
How beautiful they stand"
(So once Felicia Hemans sang)
Throughout the lovely land!

'The cottage homes of England—
Alas, how strong they smell!
There's fever in the cesspool,
And sewage in the well.

The cottage homes of England!
Where each crammed sleeping-place
Foul air distils whose poison kills
Health, modesty, and grace.
Who stables horse, or houseeth kine,
As these poor peasants lie,
More thickly in the straw than swine
Are herded in a sty?

NOTES AND QUERIES.

GERMANTOWN, PA.

TO THE EDITOR OF THE PHILADELPHIA MEDICAL TIMES:

DEAR SIR,—You will please take my name off of your list of subscribers. I have been a subscriber for some time, but have determined to subscribe no longer to medical journals. I can get reports of all of the most recent scientific investigations in the daily papers, and other news too. You are not up to the *Times*. You should have enterprise enough to supply, on demand, any doctor and every doctor with a reporter when he has any scientific thing on hand.

In New York, the great scientific investigations in regard to rabies were done up in a first-class way by the reporters of the *Tribune*,—better, no doubt, than any miserable medical journal could have done them, and with

greater profit to the world and science, and the scientist too. Medical journals are too slow for the great scientists of this day.

You had no reporter at the late scientific investigations which were made at one of our medical colleges. Those of your city subscribers who were unfortunate enough not to have been invited, and all of your country subscribers, are to this day in absolute and disgraceful ignorance of all of the phenomena of sword-swallowing, playing on a flute without any flute, holding your wind under water, and, possibly, ballet-dancing. Basely ignorant of the caution given at that meeting, some of your subscribers may attempt to open an umbrella after it had been swallowed by a patient, and thus interfere seriously with its safe and expeditious withdrawal and the patient's swallow. When these scientific investigations are introduced into the curriculum of the college, when medical students are instructed to cultivate all of these scientific things, I hold it to be your duty to report the fact to your country subscribers, in order that they may know where to send their office-students to obtain true scientific knowledge and that which is up to the day.

To your utter confusion and downright shame, I learn that there were present no less than seventeen reporters of the daily press (two from New York),—all present for the express purpose of reporting to the world the names of the great scientists who took part, and, if I mistake not, the results obtained.

Again, you had no reporters at the late scientific pedestrian feat. As a result of this neglect, I venture to predict that your subscribers will never see the scientific report which the scientific investigators will no doubt prepare from the notes taken in the ring, at the rate of five miles per hour, heel and toe on the ground; also notes taken at night, around a table, with the aid of *pasteboards*. Notes taken in this way must have value—a certain value—to the medical public, and to the investigators themselves.

If you do not do the reporting business better, you will certainly lose many subscribers.

Yours,
SUBSCRIBER.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY, FROM JULY 14 TO JULY 20, 1874, INCLUSIVE.

WAR DEPARTMENT,
ADJUTANT-GENERAL'S OFFICE,
WASHINGTON, July 10, 1874. }

Special Orders No. 149.

(Extract.)

12.—The following boards of medical officers are appointed for the examination of assistant-surgeons for promotion, and of applicants for admission into the Medical Staff, U.S.A.:

At New York City,

Surgeon JOSEPH B. BROWN,
Surgeon JOHN MOORE,
Surgeon J. H. BILL,
Surgeon B. E. FRYER,
Assistant-Surgeon A. H. HOFF.

At San Francisco, California,

Surgeon CHARLES McCORMICK,
Surgeon C. C. KEENEY,
Surgeon GEORGE E. COOPER,
Assistant-Surgeon D. L. HUNTINGTON,
Assistant-Surgeon EDWIN BENTLEY.

The Boards will assemble August 4, 1874.

The junior member of each Board will act as recorder.

* * * * *

By order of the Secretary of War.

THOMAS M. VINCENT,
Assistant Adjutant-General.

SIMONS, JAMES, SURGEON.—Leave of absence extended two months, on Surgeon's Certificate of Disability. S. O. 155, A. G. O., July 17, 1874.

WEBSTER, WARREN, SURGEON.—Relieved from duty in Department of California, and to report in person to the Surgeon-General at Washington, D.C. S. O. 154, A. G. O., July 16, 1874.

BROOKE, JOHN, ASSISTANT-SURGEON.—When relieved by Assistant-Surgeon Fitzgerald, to report at these Headquarters for assignment. S. O. 86, Department of the Columbia, July 3, 1874.

FITZGERALD, J. V., ASSISTANT-SURGEON.—Assigned to duty at Sitka, Alaska Territory. S. O. 86, c. s., Department of the Columbia.

WOODRUFF, E., ASSISTANT-SURGEON.—Granted leave of absence for thirty days, with permission to apply for ninety days' extension. S. O. 153, A. G. O., July 15, 1874.

HARVEY, P. F., ASSISTANT-SURGEON.—Assigned to temporary duty at Fort Preble, Maine, as Post-Surgeon. S. O. 140, Military Division of the Atlantic, July 18, 1874.

SATURDAY, AUGUST 1, 1874.

ORIGINAL COMMUNICATIONS.

THE NERVOUS ACCIDENTS OF ALBUMINURIA.

BY S. WEIR MITCHELL, M.D.

ALTHOUGH physicians are prepared to find cases of albuminuria exploding suddenly into horrible convulsive seizures, I think that we less readily anticipate than we should do the frequency with which slighter forms of neural disorder are apt to owe existence to the same cause.

That these also should occur is of course not surprising. What in time may give rise to the horrible motor discharges of albuminuric epilepsy may well occasion slight and yet enduring phenomena long before the anæmia and blood-poisoning have become competent to produce the graver trouble. Yet, as I have said, in attempts to account for the lesser maladies of the nerve-centres I rarely find albuminuria alluded to as a cause, while in the cases which come to me from other physicians no causes are so much overlooked as those which arise from disordered renal function.

I have been myself surprised and interested of late, in running back over my note-books, to find how many such instances I have seen; in how many persons obscure trains of nervous phenomena have found their explanation in a condition of the kidneys in which there was a steady but limited loss of albumen. The cases in question admit of little classification as regards the forms of neural disorder, which have, in fact, proved to be most various. In the rarer examples they have followed distinct cases of congested kidneys, with large losses of albumen and well-marked dropsical symptoms, but most of them have been owing, as I have just remarked, to long-continued and slight, though steady, losses of albumen due to chronic forms of renal disease, which, having caused no other notable symptoms, remained for long periods quite unsuspected.

Many cases of nerve-lesion in albuminuria are due to the consequences of co-existent heart-disease or to extensive and gross lesions due to thrombosis or arterial-wall changes; but a more common, more interesting, and less noticed group is such as would possibly yield to the eye or the lens no more obvious central tissue-change than we have from mere functional acts.

I am disposed to consider albuminuria in its various forms as ranking, therefore, among the constitutional conditions which give rise to neural disease. Like syphilis, this peculiar manifestation of its lowering and disturbing tendencies is rare, and is, indeed, more uncommon than in the case of specific infection.

Without attempting to detail all of the many cases I have seen, I shall relate such of them as are most interesting, and especially such as, from their peculiarity, do not belong to well-known clinical groups.

Headache.—I have seen many examples of headache which were owing to diseased kidneys. The pain was usually a general ache, more or less constant, and accompanied by a sense of fulness and throbbing. It was often a frontal pain, but in one case it remained steadily in the occiput. Dr. Granger Stewart (on Bright's disease) speaks of headache as a common and early symptom in cases of contracting kidney, but elsewhere not much is said of it.

Here are three cases. The first is in many ways interesting, because it was a rare form of intermittent albuminuria dependent upon some mal-assimilation which permitted the albumen to enter the blood in such a shape as to filter away in the urine. This at least may explain the case in part.

H. G., a very able and intelligent man, æt. 27, gave me this history. After a typhoid fever, four years before he consulted me, he began to have severe acid dyspepsia, followed within two months by prolonged diarrhoea, in which he passed much of the oily matters of his food undigested. This state of things lasted a year, when a long stay at the sea-side seemed to have restored his health. Soon after, he began to have headaches, which, beginning at night, soon became constant. During three years he had almost steady pain. His general health was fair, the bowels regular, and digestion often exceedingly bad. He was easily tired, and could not write or read for more than an hour a day. There was no nausea, and no pain in the back. After carefully assuring myself of the absence of any notable organic troubles in brain and heart, an examination of the urine showed this curious condition. He passed almost three quarts a day. The specific gravity varied greatly, rising high, 1024 to 1030, after meals, and falling to 1010 to 1015 in the early morning. At this time there was not a trace of albumen, but after meals, from one to three hours, it was present only rarely to a large extent. I found hyaline or faintly granular casts. The case seemed so unlike any of the forms of Bright's disease as to both interest and puzzle me. That it was due to some disorder of the albuminoids of the blood seemed the most probable belief. A total change of diet—raw beef, milk, and the use of Bedford water—proved effective. The headaches left him by degrees, and the albumen, fading away to a mere trace, entirely left the urine during a long sea-voyage.

This patient died of acute pneumonia two years later, having had no return of the albuminuria or the headaches. It will have been noted that headache was the one positive symptom on account of which he claimed my care.

In 1870 I saw a gentleman from middle Pennsylvania, who had been for two years subject to unending headache. After the most careful scrutiny I could detect no positive disease of heart, lungs, stomach, or brain. There was simply frontal headache of much severity, always worse in the morning, and greatly aggravated by reading and writing. I suspected him of having slight insufficiency of the internal rectus muscle of the left eye, and he was found by Dr. Dyer to have this defect, and also slight myopic astigmatism. As I had seen many cases of headache owing to these defects, I trusted that their correction would relieve him, but, despite the relief which correction of the optical disorders gave, the headache remained unabated. On his return to the city I examined his urine, which I had previously neglected. It contained a small amount of

albumen, with a few granular casts. For this he took iron and other treatment largely, with some relief, but up to this time the headache continues, though in lessened severity, and the albumen remains in small amount, sometimes increasing.

In the only remaining case which I shall quote, the headache occurred in a boy aged 10 years, three weeks after scarlet fever.

The pain came on suddenly at night, was accompanied with flushed face and red eyes, and had lasted a week before I saw him. Then the albuminous state of urine was detected. The urine was smoky in color, of high specific gravity, and loaded with casts. The symptoms gave way under the use of hot baths, dry cups to the loins, and diuretics. There was no œdema anywhere, and no nausea at any time. Owing to the steady return of the headache in the afternoons, it was thought to be due to malaria, and was treated with quinia. I may add, so as not again to describe this case, that it was one of a number of cases of scarlatinal albuminuria out of which were developed epilepsies beginning with attacks of petit mal.

I have notes of two other cases in which headache without dropsy or nausea was the main symptom. One of them is since dead of Bright's disease. The other is yet living, and still suffers from pain in the head, having had little ease from varied forms of treatment.

Hemiplegia—multiple attacks.—I have notes of two cases of rather rare and curious character, in which albuminuric patients were subject to numerous attacks of slight hemiplegia, never very severe or very lasting. Both were men who had been full livers and too much addicted to alcohol. I give the notes of one of these cases.

Col. S., æt. 46, a sturdy, florid man, was eight years ago attacked with pain in the back, followed by pain in the legs, insomnia, and morning nausea. After a few days, his urine, which he had not noted, as he was living in the field, became bloody. A few days after, it cleared up as to color, but was not examined for albumen. He was at the time remote from medical advice, and when some months later an army surgeon attended him, no attention was paid to the kidneys. During this period and ever since he has been rarely free from headache, which varied in site and was often of terrible intensity. A year after the first symptoms were felt, he was a good deal in the sun, and began to feel quite suddenly a weakness of the right arm, with aching pain in the hand. It became well in a week or two, but proved to be the first of many like attacks, which sometimes fell on the right arm or leg, and sometimes on the left arm. Each attack was preceded by violent pain in the head. I saw him first in the fall of 1872. At this time the right arm and leg were feeble, and there was constant pain in the right hand, with frequent attacks of slight hemiplegia with numbness of the disordered part. The right leg had slight loss of feeling. In the right hand the compass-points could nowhere be discriminated as normal. The eye-grounds were certainly too full of blood, and in both eyes a hazy outline surrounded both the veins and arteries, but there was no swelling of the disks. The right face was somewhat less sensitive than the left, but there was no ptosis or squint. Taste and smell were both imperfect, and he had a steady subjective sensation of an odor like that of brown soap. The urine was loaded with albumen, and the casts, which were numerous, were granular, and rarely of the so-called waxy appearance. There was no œdema, and but rarely any

nausea. The hemiplegic attacks were at times severe, but nearly always a week sufficed to restore to him the power to walk, there being always some lack of power and of feeling. His habits as to stimulus varied, so that at times he drank freely, and then for months not at all or but little. I suppose that the urine, having become albuminous after his first attack of inflamed kidneys, had so continued, the inflamed organs undergoing chronic changes. It is difficult to determine what direct share his habits may have had in the pathogenesis of the frequent palsies, but I presume the albuminuric condition to have been the graver element of trouble. No treatment aided him, nor do I know how his case resulted.

Local Palsies.—The following case presented itself at my clinic, and was kindly reported for me by Dr. Gerhard, who detected the retinal disease with the ophthalmoscope, and was thus led to examine the urine, the case having been at first looked upon as an ordinary instance of facial palsy.

C. D. K., æt. 23, single, a plasterer, but occasionally (for three years past) a house-painter, was seen for the first time in December, 1873, when he presented himself for the relief of an attack of severe pain in the head, from which he had been suffering off and on for three years. He appeared well nourished, was not noticeably anæmic, and was free from any paralytic symptom or symptoms of disordered vision. He was ordered to take large doses of quinia, and in a few days returned to report himself cured. Several months later he again presented himself, with marked right facial palsy. This had come on suddenly, and had been preceded by pain in the region of the right ear. For two weeks previously he had been suffering from inflammation (gouty?) of the great toe, ankle, and knee of the right side, which for a few days was so violent as to disturb his rest at night, but at the time of the occurrence of the palsy the trouble in the joints had subsided. The patient had no control over any of the muscles (supplied by the seventh nerve) on the right side of the face, and the mouth was very much drawn to the left. There was no impairment of sensation, no deviation of the tongue or palate, and no loss of electromuscular contractility.

Examination of the eye-ground revealed signs of marked retinitis, and the urine was found to be acid, to have a specific gravity of 1012, and to contain albumen ($\frac{1}{2}$) and pale granular casts.

There was no dropsy in any part of the body, and the patient was not aware of having any renal trouble; it was found, however, upon questioning him, that he had been in the habit for several months previously of rising several times at night to void his urine. There was no blue line on the gums. Vision (he stated) was unimpaired.

In regard to his family history, he stated that his parents and all other members of his family (excepting a brother who died in childhood of "dropsy of the brain") were alive, and all but his father were in good health; the latter, however, was subject to rheumatism. The patient himself never had any serious illness, excepting scarlet fever at ten years of age, followed by dropsy lasting six weeks, until the commencement of the troubles for which he sought relief.

In this case it is quite possible that the renal disorder may have been of long existence, and the cause of the headache which seemed so enduring. Nor do I feel sure that the facial palsy was directly related as effect to the albuminuria; but certainly the renal troubles acting as enfeebling agencies may have been in some sense causative.

Here again is a brief case from my clinic (reporter, Dr. Alison), in which alcoholism and renal disease must conjointly be credited with the local palsy:

P. M., aged 45, married, a tailor, was seen for the first time at the clinic of the Orthopaedic Hospital, April 8, 1874. He states that he was a hard drinker until eight years ago, since which time he has been on only three or four sprints. Has had a touch of delirium tremens. He had a breaking-out on his head when he was a child; when a boy, had "three small spots" upon his penis; never has had rheumatism.

In November last, after a hard drinking-bout, he found a spot in the sole of his left foot in which sensation was disordered. There were also shooting pains in this foot. Since that time he has had increasing numbness of the legs, and in walking he has a sense of treading on a pad. During the last month he has also had attacks of severe pain through his head.

He stands perfectly well with his eyes shut. The legs are numb to the hips, and feel as though asleep. Sensation in the right foot is not so good as in the left; still, it is but slightly impaired. The shooting pains in his toes continue at irregular intervals. He sleeps badly, and has hallucinations. He states that he has taken both phosphorus and nitrate of silver without good effect. The eye-ground is healthy. The urine is pale, scanty; specific gravity 1012; contains a heavy cloud of albumen, and a few granular casts.

Ordered tinct. ferri chlor., gtt. xx, t. d.

April 17.—Tinct. ferri chlor. increased to gtt. xx every three hours.

The iron proved of little value; the albumen did not lessen under its use, nor was the loss of power diminished by any means used in the hospital up to early in May, 1874, when, under the use of full doses of gallic acid, he gained so rapidly in every way as to be enabled to return to his usual business, the albuminuria remaining, but in much diminished amount.

Within two years I have seen two remarkable cases of loss of power to write, dependent also on renal disease. Both were treated in vain by many and varied methods, and by able physicians, who, however, neglecting to examine the urine, missed the clue which, in one case at least, led to a happy issue. These seem to me very instructive examples of the mode in which disease may be developed. A certain limited set of ganglia are over-used; then we add a constitutional drain, and the too hardly taxed nerve-cells are the first to feel the trouble. The final weakening cause might be worry or it might be malaria, but is in these present instances albuminuria.

A clerk who wrote many hours of each day had, after some years of ill-paid labor, a slight attack of measles, as to which he gave but an indefinite account. It might even have been roseola, but was at all events followed by long-continued lumbar pain, with rare nausea, which passed away after a year, but left him feeble. Soon after, he had attacks of vertigo, and during the same summer a sudden development of writer's cramp. A rest of some months relieved him, and he partially recovered the power to use his pen. The next spring the writing-muscles suffered from a sort of choreal motion when in use, and then only, but accompanied with pain in the back of the hand. When he wrote for an hour the thumb and forefinger became agitated increasingly, and at last the pen fell from their grasp. Again rest and tonics and change of air relieved him, but he still had at times pain in the back, and more rarely nausea in the mornings. The following fall he

resumed his pen-work, and in a fortnight was seized with feebleness of the pen-fingers,—a feebleness which extended to the whole arm, and was constant. At this time I saw him first, and then discovered that he had a slight trouble of the mitral valve, and a urine which was steadily loaded with albumen and which contained many granular and fatty cells. His face was pallid, and a little swollen in the mornings, and his feet were oedematous at night. Absolute rest, with tincture of iron and warm baths, soon restored the power of the limb, but the albumen is much as before the treatment, and I have little hope of permanent relief.

The curious sequence of cramps, choreal movements, and paralysis, all affecting the same groups of ganglia, I have seen once before. It is certainly of much clinical interest. I have sometimes thought that if, as in our own public schools, writers were taught to write from, as it were, or with, the arm-muscles, merely using the fingers to *hold* the pen, they might thus escape the danger of having writer's palsy or cramp; but this patient always wrote with the arm-muscles, and yet, as I have stated, he fell a victim to the disorder in question.

The second case of like nature was in a lawyer, who was called upon at times for excessive, long-continued writing. He came to me owing to increasing loss of power, which began in the index-finger and thumb, and was felt so severely as to prevent his writing for more than an hour at a time, when his hand gave out and the pen dropped. His other symptoms gave no reason to suspect renal trouble, and I only examined his urine because to do so has become a part of the routine of every examination of a new case. To my surprise, I found a moderate amount of albumen, a specific gravity of 1014 to 1020, and rare hyaline or faintly granular casts. Rest, change of air, and various iron tonics speedily reduced the albumen to a trace, at which it yet remains. As this trouble lessened, the arm improved, and for a long while past there has been perfect power to write for several hours on a stretch. His general health has also improved greatly.

I could readily add to these other examples, more or less striking, of local paresis or distinct palsies observed in connection with albuminuria. I find among my notes some curious instances of what, having been regarded as hysterical disorders, proved to be traceable to renal disease.

In one remarkable instance, a married lady, æt. 29, had prolonged fainting-fits. They began during her unmarried life, and were alike notable for being most profound, as well as for their frequency and suddenness. She passed through a first pregnancy with no graver symptoms, but the attacks, continuing, began to be associated with occasional nausea, so that when the nausea was the worst the fainting-spells were most common and most intense. Then also the general vigor and power of endurance, never great, began to fail quite notably. At this time I saw her first, and it was then found that she had a steady loss of albumen, but not in large amount.

I cannot flatter myself that the after-treatment much lessened this flow, but it exerted so favorable an influence on her general health that, despite the still constant loss, she rose above the possibility of attacks, and by steady care of her health has remained in a very satisfactory condition.

The following case is on many accounts interesting, and especially so because absolute loss of taste from disease is extremely rare:

Mr. McM., æt. 30, hotel-clerk, and thus occupied for ten years; two years ago hurt his side by a fall, and had slight pulmonary hemorrhage. In May and June he had a succession of colds, and at last a violent spell of renal congestion, with bloody and scanty urine, horrible headache, and high fever. There is little need to linger on the treatment. The attack was nearly fatal, and after much active treatment the first relief was from a prolonged pack. The albumen increased with the larger flow of urine, and at the second month was in large amount; specific gravity 1014 to 1019; granular casts abundant; pain in back and legs, and slight œdema of ankles and face. The attack took place in March. In May he lost his sense of taste entirely, and also in part that of smell. So absolute was this loss that he could not tell quinia from sugar, or vinegar from milk, if we were careful to prevent him from using any of the small remnant of olfactory power. Until he went away from this city in the fall this curious condition remained unaltered. Mr. McM. recovered his health entirely after a prolonged stay in the mountains, and is now, many years having passed, in full personal vigor.

I have twice seen cases which were supposed to be pure examples of overwork,—both lads at college,—in whom I found albuminuria. One of these was a fine young fellow, who, near to the close of his college career, began to find his power to study lessening, while at the same time he was less able to get to sleep, and quite unable to stay asleep very long. Rest did no good, and at last I was asked to meet his physician. The lad proved to have a moderate amount of albumen in a urine of quite high specific gravity and containing many hyaline casts. To my great satisfaction, he perfectly recovered. The other boy was less fortunate.

Acute Mania.—Neither is it very rare, I suspect, for sudden and complete cases of renal congestion to result in attacks of acute mania; at least I have seen such examples.

More rare must be instances like the following:

Several years ago I was asked to visit Mr. M., æt. 40, a well-known insurance agent, who was staying with his wife and family at a hotel in this city. Mrs. M. and two of his friends assured me that his habits as to stimulus were unusually good.

His wife stated that a week before my visit he had begun to be weak and feverish, and to have at night copious sweats, and quite suddenly complete insomnia.

When I saw him, he was flushed, and his pulse 130; breathing 35; no lung- or heart-disease. He had passed one week without sleep. His manner was quick and wild, his hands in constant tremor, and he was haunted by delusions as to animals,—chiefly as to dogs. I do not think any one would have hesitated a moment to diagnose the case as the delirium of alcohol. Indeed, it was some time before I could credit the indisputable evidence which prevented me from holding this belief. He used stimulants rarely, tobacco in great moderation, and he had been subjected to no mental shock. A more careful study of the case showed him to have a large amount of albumen in his urine, with numerous casts and a little blood. He slowly recovered his mental health and the power to sleep, and left the city some months later much improved, but still passing albumen in large amount.

I think it needless to multiply cases further, believing that I have shown how varied may be the neural phenomena arising out of the various disorders known to us collectively as albuminuria.

CASES CURED BY ELECTRICITY.

BY HUGO ENGEL, M.D.

NIEMEYER has been, I think, the first author in this enlightened age of improved diagnosis who said that we should now try to improve our therapeutics by empiricism based upon sound knowledge, *i.e.*, with the aid of our advanced diagnostic art to note carefully the effect of our therapeutical agents, so that certain conditions under which remedies act can be specialized, and their efficacy established by trial.

Such a way of recording trustworthy facts was, a short time ago, less reliable, as our diagnosis was so uncertain; and, although we are even now far from being perfect in it, we can better rely at present upon records of cases.* In consequence of this, the effect of our therapeutical agents can be better observed. In my opinion, it is the duty of every physician to spread before the fraternity any facts which might tend to improve our knowledge of healing, and not to think that “*natura sanat et medicus curat*” implies that nature will always do the first, even when the physician fails to do the second.

I have studied for a considerable time the effect of treatment by electricity in certain cases which came under my observation, and publish to-day some of them in the *Philadelphia Medical Times*, that the treatment may be tried by the profession, and its effect, observed on other cases, recorded.

Pollutions.—A case of frequent involuntary discharge of semen, that had baffled all routine treatment and all dietetic and psychical directions, induced me to try electricity. After repeated failures of other kinds, the following galvanic treatment was successful. I placed one electrode, armed with the positive pole of a constant current (16 cells), in the middle of the neck on the spinal column (having before thoroughly wetted the skin and the leather covering the electrodes), and the negative on the os sacrum, and kept the electrodes in this position for three minutes, thus producing a constant current. Then, with the same precaution, the positive pole was placed on the perineum, and the negative on the dorsum of the penis near the symphysis. The negative was kept there for about a minute, and then slowly moved up towards the glans, and kept there for the same time, while the positive was not changed in its position. The treatment is, as the reader will observe, similar to the one recommended by Meyer. In five cases treated thus, an amelioration was observed the first night, and after from nine to twenty-two applications the cure was established. To enable the reader to form a correct idea of the cases, I publish two of them.

Case I.—Charles S., æt. 24 years, strong, but pale-looking, had practised onanism from his fourteenth to his twentieth year, “not oftener than once a day.” For the last four years he has not been guilty of the practice, but has had frequent discharges of semen, which have

* In this respect we decidedly owe most gratitude to Prof. Da Costa, whose work has more than any other promulgated the advanced knowledge of medical diagnosis.

come during the last year once, and sometimes twice, every night.

Case well after twelve applications of the constant current, applied at first every day, then every second day, then every third day, and so on. Has now (over a year) no pollutions if he has connection with a woman every two weeks, which he was unable before to do. If he omits the coitus, has a pollution about every three weeks.

Case II.—Fred. M., æt. 28 years, healthy-looking, with a history similar to that of Case I. Complained of repeated pollutions (one at least every second night), "which weakened him very much," and when he had tried to enjoy a coitus "the discharge would come right away" as soon as the penis had entered the vagina, "and the penis would then double itself." Cured after sixteen applications.

Fred. M. is now married, and has a child.

The other cases were similar. In no case was there any discharge during daytime, except in one, where the patient had slept in the afternoon, and in all cases there were dreams and a voluptuous feeling connected with the pollutions. All these cases, therefore, were in the primary stage. Cases of longer standing I have not seen since I have been employing electricity. In two of the cases there were small external hemorrhoids.

The most careful examination could not reveal any other cause of the complaint than masturbation, except, perhaps, the irritation from contiguity; but here the treatment was successful, and the hemorrhoids still remained.

Nocturnal Incontinence of Urine.—Owing to the surprising results I had in some cases of nocturnal incontinence of urine of children, I have been overrun with children who have been sent to me for the treatment of this complaint. Of the different ways of using electricity in these cases, I have found the following to be invariably successful. A constant current of six cells (stable) is sent through the vertebral column for three minutes, then the positive pole of a faradaic current (medium strength) is placed over the symphysis, after having thoroughly wetted the skin and the electrode, and the negative pole introduced into the urethra as far as the entrance into the bladder,—no farther. The electrodes are kept in their position for five to eight minutes.

The following case will show the effect, and as I have treated now twenty-three cases successfully (all children between 4 and 10 years), I think I can speak from experience:

Anna V., æt. 8 years, delicate health. Her mother says that the girl always suffered from nocturnal incontinence of urine, and in cold weather much more (very naturally). She had whipped the child for doing so (foolish and barbarous), and had tried "a lot of medicine and doctors," but of no avail.

October 20, 1873.—Had passed her urine last night involuntarily, as she always did during night. Treatment by electricity (as above, six minutes) commenced.

October 21.—Patient passed no urine last night; wonders that she "need not pass water so often any more," and it seems to her as if it flows much stronger, with more force. Current again applied for five minutes.

October 22.—No nocturnal incontinence last night. The little girl looked much brighter, as might be imagined, from the feeling that she was going to lose "that nasty habit." Treatment omitted.

October 23.—The same. Current applied for three minutes.

October 25.—The same. Patient felt a desire to urinate at 1 o'clock A.M.; she got out of bed and urinated. Current applied for five minutes.

October 28.—There had been no farther symptoms of incontinence. Current applied for three minutes.

November 2.—The same. Current applied for two minutes.

November 20.—The same. Current applied for a few minutes, and patient discharged.

April 12, 1874.—I saw the patient's mother to-day, who informed me that her daughter was "totally well, and gaining in health every day."

This is one case: certainly not all are so favorable. Sometimes this treatment has to be continued for two weeks every day. As a rule, where there has been no symptom of incontinence for three consecutive nights, I omit the application of the galvanic current for one day, then for two days, and so on. Here the personal judgment must decide.

These cases do not need any further comment. The diseases are described in all their different forms in so many medical books that it would be only a repetition to say more about them here. How successful the treatment will be in more complicated cases, further experiments will have to show.

NOTES OF HOSPITAL PRACTICE.

UNIVERSITY OF PENNSYLVANIA.

SERVICE OF DR. H. C. WOOD.

Reported by Dr. LOUIS STARR, Chief Assistant.

LOCAL PALSY IN LEAD-POISONING.

CHARLES M., aged 42, a painter by occupation, applied for treatment at the dispensary on January 8, 1874. He is married, has four healthy children, is perfectly temperate, and has always enjoyed good health until about two months ago, when, while working against time, his right arm became very much fatigued, he had temporary wrist-drop, and was obliged for a day or two to work entirely with the left arm, which he is able to use almost as well as the right. Early in December, 1873, after a period of unusually hard labor, he began to notice numbness and a tingling sensation in the index-finger of the right hand; this gradually extended up along the inside of the arm to the elbow, and then involved the whole hand. The tingling, which was slight at first, slowly became more severe, and the arm grew so feeble that one week before coming to the dispensary he was obliged to give up work. He stated that he had been careful as to the cleanliness of his hands, although in using putty (often colored with white lead) he was in the habit of forcing it into the nail-holes with the thumb, and then smoothing it off with the index-finger instead of employing the ordinary putty-knife: the friction this occasioned frequently wore the skin off the end of the finger, leaving a raw and sometimes a bleeding surface. For several years past he has, while actively engaged at his trade, voided large quantities of urine, the amount passed often ranging as high as three pints during a single night. It had at such times the peculiar violet odor due to the absorption of turpentine, but was always normal in appearance, and he has never had anasarca or pain in the region of the kidneys.

When he came under observation there was a distinct blue line along the margin of the gums, the tongue was

coated, the bowels constipated, and there were some dyspeptic symptoms, though no tendency to colic.

The urine presented the following characters: quantity and odor normal, reaction acid, color light yellow, large deposit of uric acid crystal on standing for a few hours; no albumen or tube-casts could be detected.

The right arm was found on measurement to be slightly larger than the left, the muscles being firm and exceedingly well developed; there was no wrist-drop, but considerable loss of power in both the flexors and extensors of the fore-arm, and some want of co-ordination in the muscles of the hand; the latter was most markedly exhibited when he endeavored to pick up a small object between the thumb and index-finger. The numbness and tingling were most marked in the index-finger, and from this position extended over the whole hand, and up the arm as far as the shoulder. The skin covering the palmar surface of the first joint of the index-finger was very thick, and almost devoid of sensibility. No alteration of the surface-temperature of the arm was appreciable to the hand; all the muscles responded well to the faradic current, and the electro-sensibility of the skin remained normal.

He was directed to bathe the arm night and morning in a strong solution of salt and water, to return three times a week for electrical treatment, and to take internally gr. v of potass. iodid. in f3ii of infusion of gent. comp. three times daily, with moderate doses of magnesiz sulph. before breakfast in the morning until the constipation was relieved.

On January 13 the iodide of potassium was increased to gr. v four times daily, and lin. saponis camph. ordered instead of the salt-baths; under this treatment the condition of the arm improved steadily, the blue line began to fade from the gums, and the bowels became regular.

On the 20th all internal medication was discontinued, and the sole reliance placed upon faradization of the affected muscles and the application of the brush to the skin of the arm and hand. By February 6 the numbness and tingling had disappeared, the muscular co-ordination had returned, and the patient complained merely of weakness in the arm; strength was restored rapidly, and on February 26 he asked to be discharged, as he felt himself well enough to resume work.

TRANSLATIONS.

THE ACTION OF OXYGEN UPON REFLEX EXCITABILITY.—Dr. Ananoff gives (*Centralblatt für Med.*) results arrived at by him from experiments which he performed with the view of investigating this subject. Two rabbits of like size were chosen, and to them poisonous doses of strychnia were administered. One of them was then exposed to pure oxygen, while the other remained in the atmosphere. At the expiration of twenty-eight minutes the rabbit which was inhaling pure oxygen had not had any of the convulsions which precede death from this poison. The supply of oxygen was then stopped, but death did not occur until ten minutes later, and was then attended by convulsions which were not violent in character. The animal which had been permitted to remain in the air gave evidence of convulsions three minutes after the poison had been swallowed, and in seven minutes was dead. To prove that this difference was really due to the influence of the oxygen and not to the pressure upon the gasometer whence the gas was supplied, a similar experiment was performed, except that, for the oxygen previously used, atmospheric air under pressure was supplied to one animal, while the second, as before, breathed the outside air. After seven minutes the first animal manifested convul-

sions when irritated, and at the end of twenty minutes was dead; the second died in six minutes. In a third experiment, one animal breathed air, and the other oxygen, but both gases were under pressure. The first lived but twenty minutes, while the second lived thirty-two. From these results it must be concluded that no certain and positive effect must be expected except from the supply of pure oxygen. W. A.

ALTERATIONS OF THE SPINAL CORD AFTER INJURIES TO NERVES (*Centralblatt für Med.*).—In addition to those alterations in the nerve-substance of the cord following resection of the sciatic nerve which have been already noted, Hagem found that in those animals which survived the experiment more than two months there occurred a progressive muscular atrophy which began in the muscles of the posterior extremity of the uninjured side and extended to those of the anterior extremity of the same side. This was due to perimenigitis caused by hemorrhage and a general central myelitis. This latter affection was characterized by hyperæmia of the gray matter, into which there were numerous extravasations of blood. There was likewise an exudation into the central canal, and a characteristic degeneration of the ganglion-cells which proceeded to entire destruction. Similar changes were found in some cases when the lesion had been but a simple section of the sciatic nerve. W. A.

GROWTH OF BACTERIA UNDER LISTER'S DRESSING.—H. R. Ranke (*Centralblatt für Chirurgie*), in seeking to answer the question as to the presence of Bacteria in wounds treated by the antiseptic method, made during the month of May many observations on cases under treatment in the clinic at Halle. Many of these cases were amputations in which there was neither fever nor suppuration, so that it cannot be objected to his results that the cases were those in which the dressing had not been successfully applied. In all the cases but one which were subjected to examination some forms of Bacteria were found. The figures presented by them were various, those of middle and small size being in less number than the larger. It was remarked that the micrococcus was found at the first renewal of the dressing, twelve hours after the operation. W. A.

CONDURANGO.—Dr. Alfred Obalinski, of Cracow, reports (*Centralblatt für Chirurgie*) successful results in two cases of epithelial cancer treated by condurango, both internally and locally. The first patient, a woman aged 80, had a small epithelial cancer (ulcus rodens) on the under eyelid; the second, also a woman, aged 50, had an ulceration of a similar character of the size of a bean, which had been noticeable for three years and had been already treated by caustics. Six weeks later both patients were seen again, and in both cases the ulcerations were completely cicatrized. W. A.

THERAPEUTIC NOTES.

IODOFORM AS A TOPICAL APPLICATION, PARTICULARLY IN VENEREAL DISEASES.—MM. Dubrisay and Pelletan, in independent brochures upon this subject, arrive at the following conclusions in common (*Jour. de Dermatol. et Syph.*).

1. Iodoform is a local anæsthetic.
2. Applied in the form of a powder it cicatrizes wounds rapidly.
3. It is especially indicated in small superficial atonic wounds, or those having a tendency to phagedæna, soft chancres, suppurating buboes, syphilitic onychia, syphilides generally, varicose, scrofulous, and cancerous ulcers.

4. It operates more surely and promptly than other therapeutic agents ordinarily employed in the cicatrization of ulcerating syphilides, under whatever form they may present themselves.

5. In the treatment of soft chancre it is in some sort a specific in the promptitude with which it causes cicatrization without pain.

6. In the treatment of simple or virulent buboes (non-specific) it may be employed in the form of ointment as a resolvent during the first period with more success than a blister or tincture of iodine. During the period which succeeds the opening of the sore it hastens rapid cicatrization of the wound.

7. In the case of soft chancre, of ulcerating syphilides, and of bubo, when the suppuration is abundant it is preferable to commence the treatment by solution of iodoform in glycerin and alcohol. The iodoform in powder may be used later.

8. The employment of iodoform in syphilitic affections does not do away with the necessity of using internal treatment.

9. The rapid cicatrization brought about by iodoform is due—1, to the simplicity of the dressing, which does not irritate the diseased parts; 2, to absorption of secretions by the powder; 3, to its antiseptic properties, particularly when it is dissolved in glycerin and alcohol; 4, to the presence of iodine, which acts favorably on syphilitic ulcerations of all kinds.

HYPODERMIC INJECTIONS OF MORPHIA IN STRANGULATED HERNIA.—Dr. A. Szatvory reports (*Jour. de Thérapeut.*) three cases of strangulated hernia, where, taxis having failed, an injection under the skin of a few drops of a solution of morphia containing about $1\frac{1}{2}$ grs. to the drachm of water produced such relaxation around the strangulated parts of the intestine that another attempt at taxis resulted in reduction of the hernia.

POST-PARTUM HEMORRHAGE (*The Canada Lancet*, April, 1874).—Dr. Augustus Jukes recommends in cases of post-partum hemorrhage the injection into the cavity of the uterus of dilute alcohol. He has thoroughly tested its efficacy in such cases, and has never known it to fail, or, on the other hand, to produce any bad results.

The following are the only requisites for its success: *First*, that it be not too long delayed.

Secondly, that the uterus and vagina be first carefully emptied of all retained matter, whether clots or placenta.

Thirdly, that the tube be passed fairly within the cavity of the womb, so as to insure a full stream reaching its interior. Where this is effectually accomplished, the action of the muscular walls of the uterus is often so rapid and energetic that the fluid is at once and violently ejected.

NITRITE OF AMYL AS AN ANTIDOTE TO CHLOROFORM (*The Richmond and Louisville Medical Journal*, June, 1874).—Dr. William C. Dabney has made some experiments with a view to determining whether or not nitrite of amyl, by its effect as a cardiac stimulant, would be of service in cases of chloroform narcosis. In three out of four animals the amyl produced a decided increase in the frequency and force of the heart's beats,

and they recovered when death was apparently imminent. In the fourth no effect on the heart's action was noticed, and the animal died.

STRYCHNIA AS AN ANTI-EMETIC (*The Canada Lancet*, April, 1874).—Dr. Thomas E. Dupuis reports a case of obstinate vomiting in a delicate female, which was absolutely uncontrollable, and continued until the most extreme prostration had occurred. After nearly all other remedies had been tried unsuccessfully, the following solution was given in drachm doses every two hours: R *Liquoris strychniæ*, \mathfrak{M} xx; *aquæ*, \mathfrak{z} iv. The effect was very sudden and decided: the vomiting stopped entirely within a few hours, and the patient soon recovered.

GELSEMINUM IN FACIAL NEURALGIA (*The British Medical Journal*, May 2, 1874).—Drs. Sawyer and Mackey highly recommend the employment of gelseminum for the purpose of relieving pain, especially in branches of the fifth nerve. The preparation used is a tincture made from two ounces of the coarsely-powdered root macerated in a pint of rectified spirit; dose, five to twenty drops. The evidences of the physiological action of the drug are loss of sight, double vision, headache, and paralysis.

ELEGANT FERRUGINOUS PREPARATION (Prof. Goodell).—The following offers simply the most elegant and efficient ferruginous preparation we know of:

Take of tincture of the chloride of iron three fluidrachms, dilute phosphoric acid half a fluidounce, syrup of lemons three fluidounces; mix. A whitish preparation, pleasant to the taste; to be exhibited in a dose of a dessert- to a tablespoonful.

VOMITING CONTROLLED BY TOBACCO-SMOKE.—A young girl not pregnant, suffering from severe and uncontrollable vomiting, under Dr. Beaumetz's care at the Hôtel-Dieu, was, after the ineffectual trial of various remedies, ordered to smoke a cigarette after each meal. This, so long as its use was persisted in, seemed to check the vomiting entirely.

ANTI-CANCEROUS SOLUTION (Giordano).—

R *Acid. citric.*, \mathfrak{z} i;
Aquæ destillat., \mathfrak{z} i \mathfrak{z} ii.

M.—Pieces of charpie soaked in this solution and laid upon cancerous ulcerations act as a detergent and delay the progress of the disease.

Dr. EBSTEIN recommends the use of atropia in salivation. In his hands one-fiftieth grain daily, increased in the course of eight days to one-twelfth grain internally, had a decided effect in lessening salivation in a case of hemiplegia. Hypodermic injections of the same drug in the region of the neck had a still more favorable effect.

TOOTHACHE.—Dr. Q. C. Smith praises the following most highly (*London Med. Record*): Take of carbolic acid, saturated solution, chloral hydrate, saturated solution, paregoric, fluid extract of aconite, of each an ounce; of oil of peppermint half an ounce; saturate the pledget of cotton or a piece of sponge, and tightly pack in the cavity.

An artificial ferruginous mineral water may be made by the following formula:

R *Ferri citrat.*, gr. xvi;
Syr. limonis, $\mathfrak{f}\mathfrak{z}$ xxvi;
Artificial Seltzer water, ad Oi.

This makes an agreeable mixture, and can be modified by the use of ordinary soda-water procurable from any apothecary. It is not necessary that the mixture should contain much air, and if kept in a cool place the bottle containing it may be opened several times without depriving it of flavor.

PHILADELPHIA MEDICAL TIMES.

A WEEKLY JOURNAL OF

MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY

J. B. LIPPINCOTT & CO.,

715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, AUGUST 1, 1874.

EDITORIAL.

INTRAVENOUS INJECTIONS OF CHLORAL IN HYDROPHOBIA.

AS most of our readers are no doubt aware, the intravenous injection of chloral has not only been proposed by French physicians, but carried out in several cases of tetanus, and even as a means of producing anæsthesia for surgical purposes. At the séance of the Société Médicale des Hôpitaux, June 26, M. Bucquoy reported a case of hydrophobia in which he had exhibited the drug in this method. The patient was a man who entered the hospital May 31, having been bitten four weeks previously by a dog. On May 29 he first began to suffer from malaise and total loss of appetite. At the time he came under M. Hanot's care he complained bitterly of pain in the arm and the finger which had been bitten, and of sleeplessness. His skin was hot, pulse 120, and any attempt at drinking, or even the sight of water in a glass, produced violent hydrophobic spasm of the pharynx and thorax.

It having been determined to practise the intravenous injection of chloral, the arm was tied up as for bleeding, and the fine point or needle of a syringe thrust directly into the vein. The syringe contained 1 gramme of chloral dissolved in 10 grammes of water, and ten syringefuls were given in an hour and a half. At the end of this time symptoms of "chloroformic excitation" had replaced those of the disease. Nevertheless the injections were repeated until, in about two hours, 13 grammes of chloral had been injected. The patient fell asleep,

and slept tranquilly until the evening, when he awoke in a condition of drunkenness, and was able to drink without spasm. He voided some bloody urine, but passed a quiet night, sleeping at intervals. The next morning the symptoms recurred, and about 1 P.M. the injections were repeated, 20 grammes of the drug being thrown into the left saphenous vein. This produced a deep sleep, which lasted two hours, when the patient was seized with a violent tetanic spasm, in which he died. The chloral did not affect the temperature very sensibly. At the autopsy the veins made use of were free from clots.

In the course of the discussion which followed this report, M. Bucquoy stated that the canula had been allowed to remain during the whole of each operation, and M. Féréol promised to report to the Society a case in which hydrophobia was developed two years after the reception of the bite.

WHAT NEXT?

IN a recent editorial we animadverted upon the methods of acquiring popular fame and practice which are becoming fashionable in New York. It may be that all our old notions of propriety are wrong, and that as the people are in reality to a great extent the arbiters in medical matters, so far at least as concerns *pecuniary* success, therefore it is better to spread before them all our knowledge and all our differences, so that a man may make up his judgment from the *Tribune* or other of his daily papers who is the best physician or surgeon of his neighborhood. Out of the attrition of the daily life of great cities usually come the sparks that light up revolutions; and where should a revolution start in this country if not in New York? Is the profession there ready for revolution?—ready to cast off the old garments of respectability and to put on the new livery, whose color and fit are so close to that of the servants of quackery? We should judge not; yet time and again long articles appear in the *Tribune*, undoubtedly written by medical men, and undoubtedly written for the purpose of aiding those whose praises they sing. This is done, too, seemingly without a protest from any one; not a word against it in the New York medical press, not a whisper in the societies,—at least that reaches the outside world.

The consultation-room has been held the most sacred of all places; but in New York, when a man differs from his fellows, he, at least sometimes, goes for solace to the *Tribune*, and details in long, well-written articles the discussions of the consultation-room, the superiority of his own merits, and the

grand improvements he has made in medical science ; or, if he does not actually do this, he tells his subordinate all about the circumstances, and he does it for him.

The recent vagaries in regard to rabies are still fresh in the minds of men ; but we have been incited to writing the present article by reading nearly two columns in the *Tribune* of July 14, detailing how Dr. William F. Fluhrer thought an arm could be saved when Dr. James R. Wood and others thought it could not, and how Dr. Fluhrer did save the arm, etc., etc.

There are few things more pitiable than a man struggling vainly in a flood. We do not covet a martyr's destiny, and if the profession decide that the necessities of to-day require the appropriation of the quack's method by the regular profession, we have nothing to say ; but when the spirit and letter of the Code of Ethics are opposed to such doings, it is but fair that all members of the profession in good standing should be forced to comply with this code.

AS most of our readers probably know, Miss Jex-Blake, the lady who has won such world-wide notoriety as the champion of her sex in connection with the University of Edinburgh, was "plucked" in her recent examination. The indignant young lady rushed into print for solace, charging her examiners, in a letter to the editor of the *London Times*, with unfairness, and asserting with characteristic but unfeminine modesty that she was "thoroughly prepared." Owing to the circumstances of the case, the examiners decided it necessary to reply to this letter, and, in a subsequent issue of the same paper, published a document which should, if the thing be conceivable, abash Miss Jex-Blake. The subjects of examination were chemistry, botany, and natural history. Her papers "were carefully examined by six examiners (three of whom were professors), and they unanimously agreed that the answers were extremely defective on every subject."

DR. HOOKER, of Kew Gardens, than whom there is no higher authority upon such matters, has officially informed the English colonial office that the sanitary virtues of the *Eucalyptus globulus* have been greatly exaggerated.

IN the recent exhibition at the Royal Academy, London, a number of etchings and oil-paintings, some of them said to be of great merit, the work of English surgeons and physicians, were on exhibition.

CORRESPONDENCE.

TO THE EDITOR OF THE PHILADELPHIA MEDICAL TIMES:

DEAR SIR,—Dr. Berkart, in the *London Lancet* of March 28, informs the readers of that journal that he first conceived the idea of injecting pulmonary vomicae as far back as 1872.

I think it is due Dr. William Pepper, of this city, to state that he informed me and others in the *spring* of 1867 that he believed it possible to treat phthisical cavities with a fair prospect of success by injecting medicines into them through the thoracic walls, and at the same time said that he would make the attempt as soon as the proper opportunities should present themselves.

I make this statement because there seems to be some doubt as to who is entitled to the credit of first suggesting this plan of treatment.

Very respectfully,

R. G. CURTIN.

PHILADELPHIA, July 15, 1874.

PROCEEDINGS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

THURSDAY EVENING, MAY 28, 1874.

THE PRESIDENT, DR. WM. PEPPER, in the chair.

DR. HUTCHINSON presented, by permission, without a written history, as he reserved the case for publication elsewhere, several specimens of *lymphadenoma*, removed from the body of a young man who had died a few weeks before in his wards at the Pennsylvania Hospital. More than a hundred lymphoid tumors could be counted distributed beneath the skin of various parts of the body, the largest being situated over the sternum. There was complete paraplegia, which Dr. Hutchinson believed, during the life of the patient, to be due to compression of the spinal cord by a tumor similar to the tumors on the surface, and the autopsy showed that his diagnosis was correct, a growth being found within the spinal column on a level with the seventh and eighth vertebrae, almost completely surrounding the cord. A microscopic examination of the blood during life showed a great increase of the white corpuscles.

Dr. JAMES TYSON said an allusion of Dr. Hutchinson's suggested an explanation of the origin of these tumors in different parts of the body, where there are apparently no elements of a lymphoid nature. Dr. H. had mentioned glandular enlargements on the conjunctiva. These doubtless had their origin in the so-called *trachoma* glands or lymph-follicles of the eyelid, first described by Bruch in the conjunctiva of the lower lid of oxen, and by Kleinschmidt in man and the domestic animals. By Wolfring, Stromeyer, and Blomberg they were considered pathological structures, and were named *trachoma* glands by Henle. These glands have had their lymphatic characters well determined, and as they were discovered in situations long thought devoid of such lymphoid elements, so, doubtless, other situations, as the nervous tissues, abound in lymph-centres and paths, which, from irritation, are capable of being developed into lymphatic bodies as large as any presented this evening, though previously there might have been no evidence, to ordinary methods of demonstration, of their presence.

Dr. JOSEPH G. RICHARDSON inquired of Dr. Hutchinson whether he had estimated the proportion of colorless corpuscles to the red before the patient's death.

Dr. HUTCHINSON replied that he had not.

The PRESIDENT said this was important in relation to the more usual forms of leucocythæmia. It is well known that there is a lymphatic variety in which the spleen may be but slightly affected, but it is entirely unknown that the spleen and liver should be unaffected where there is such intensity as in this. It is also well known that in some cases of lymphadenoma there is no increase in the white corpuscles of the blood. Such a case had come under his own observation, in which there was enlargement of all the lymphatic glands and the development of lymphoid tumors in the viscera. The spleen was also enlarged, and there were in it white patches, such as are found in ordinary cases of leucocythæmia, but there was no increase in the white corpuscles up to the time of the patient's death. Since it is well known that this increase is apt to be a progressive one, and since a moderate degree of increase in the number of the white corpuscles was observed some time before death in the present case, it would be very interesting to learn whether marked leucocythæmia was not developed later in the course.

Dr. HUTCHINSON said, while it is generally admitted that the increase in the number of white blood-cells in this disease is progressive up to the death of the patient, there is at least one writer of distinction, M. Jaccoud,* who takes an opposite view. In his opinion, the cells are prevented in many instances from reaching the blood-vessels, in consequence of the lymph-ducts being compressed by the increased growth of connective tissue which is sometimes superadded to the hypertrophy of the true glandular structure. Cases are, moreover, reported in which the increase of the white cells was not observed, or, having been observed, has afterwards ceased to exist.

The PRESIDENT said he was familiar with the paper referred to by Dr. Hutchinson, and could merely say that as yet the statements there made had not been substantiated, and that they certainly did not correspond with the results of his own examinations in quite a number of cases of leucocythæmia.

Dr. RICHARDSON said that in a recent case which died at the Pennsylvania Hospital he had found *one white to two red* corpuscles ten days before death. After death, the proportion was *two white to three red* corpuscles.

Dr. MORRIS LONGSTRETH said he had examined the blood after death, in Dr. Hutchinson's case, and, although he had not counted the corpuscles, he was confident that the white were more numerous than in health.

The PRESIDENT said the case to which he had alluded had been under treatment for some time at other hospitals for lumbago. He had had more or less deep-seated pain, with periodical intense exacerbations, radiating in the course of the lumbar nerves, and occasionally extending down the sciatic nerve. At the time at which he first saw him, however, there was evident enlargement of the submaxillary glands, which progressed with the enlargement of other glands.

In that case the enlargement did not go on to encroachment upon the spinal cord: still, although there was no palsy there was great weakness of the legs; and it was very evident that both the severe pain and the impairment of power were dependent upon the pressure of the enormously enlarged abdominal glands upon the nerves emerging from the spinal foramen.

Dr. F. P. HENRY presented the following specimens, with their histories:

I. Gastric ulcer.—A. H., æt. 19, admitted to the Episcopal Hospital April 18; had been sick for about three months before admission. It was impossible to get from her anything like a clear history of her case. On entry, she was much emaciated and jaundiced. There was intense pain on pressure over the epigastrium, and great pain over the same region after eating. When I took charge of the case on May 1, the girl was evidently sinking, and suffered such intense pain that the treatment from that time consisted almost solely in the use of hypodermic injections of morphia. She died on the 13th of May.

At the *post-mortem* examination a small circular ulcer was found near the cardiac orifice of the stomach. The lungs, heart, and kidneys were healthy. The liver weighed five pounds, was indurated and coarsely granular on section. It appeared to be in the first stage of cirrhosis.

The immediate cause of death seemed to be heart-clot. Firm, yellowish-white clots were found in both ventricles. There was no appearance of pulmonary emphysema, as was observed by Dr. Packard in a case of sudden death from heart-clot recently reported by him to the Society, but the lungs presented an anæmic appearance, as though the supply of blood had been gradually diminished.

An interesting feature of the case is the occurrence of cirrhosis of the liver with gastric ulcer. Rindfleisch attributes the cause of gastric ulcer to the occurrence of "small hemorrhages from the superficial venous trunks of the gastric mucous membrane," caused by "the temporary stagnation of the blood's afflux" in the act of vomiting. "The hemorrhagic infarction becomes a caput mortuum, its organic connection with the healthy mucous membrane is destroyed, and the actual separation only a question of time." This separation is greatly facilitated by the action of the gastric juice, which immediately attacks the dead mucous membrane.

In cirrhosis of the liver there is a constant obstruction to the return of venous blood from the stomach through pressure upon the portal vein, rendering hemorrhage extremely liable to occur during the act of vomiting or even independently of it. I am not aware that any frequent connection has been noticed between the two diseases, but, if so, it would seem to add additional weight to Rindfleisch's theory of the pathology of gastric ulcer.

II. Dysenteric inflammation, with cystic kidneys.—P. D., seaman, æt. 62, was admitted to the Episcopal Hospital on the 2d of May. He had been on a voyage to the French islands on the east coast of Africa, and during the passage home he had suffered from diarrhœa, with colicky pains in the stomach and bowels, and occasionally passed blood by the rectum. On the voyage home, five of his shipmates and the mate died, after complaining of the same symptoms.

The patient grew steadily worse, remedies having no control over the dysentery, and he died on May 12, ten days after admission. Three days before death he passed a quantity of blood, estimated at a quart *by the nurse*, per rectum. The *post-mortem* revealed a healthy state of all the abdominal viscera except the large intestine and kidneys. There are no ulcers visible upon the mucous membrane of the colon and rectum, which is swollen and greatly congested. The kidneys present numerous cysts of large size.

During life the urine was not examined, no symptoms pointing towards disease of the kidneys. The patient was conscious up to within two hours of his death.

Dr. BERTOLET presented a piece of ham infested with *trichina spiralis* that had been sent to him for microscopical examination. To the naked eye it did not present any abnormal appearances, although the muscular fibres were quite densely packed with the trichinæ:

* Leçons de Clinique Médicale faites à l'Hôpital Lariboisière.

this was easily accounted for by the fact that many of the parasites were still in the migratory state; others again were encapsuled, but the surrounding membrane had not yet been rendered opaque and thus visible to the unaided eye as white dots by the deposition of calcareous matters. No trichinae were found in the layers of fat surrounding the muscular tissue. The fibres of the latter still presented their transverse striations, except in the immediate vicinity of the capsules, where they were cloudy and disintegrated, while at the same time the sarcolemma and interstitial connective tissue were greatly thickened.

He stated that it was presumable that the animal had been slaughtered within a brief time after being infested. It had been ascertained by experiment that from one to three months must elapse before the capsules become opaque.

Portions of this same ham, which had been cured and smoked, were eaten uncooked by a family at Harrisburg, all the members of which were taken violently ill upon the third day, one of the cases terminating fatally in less than a week's time. The communication received did not state what symptoms the patient had presented, but generally, in those rare cases where the disease proves so rapidly fatal, there is violent gastro-enteritis, with more or less pronounced peritonitis. Usually trichinosis assumes a much slower progress, giving rise to intense muscular pains and oedema, simulating muscular rheumatism.

Dr. DE F. WILLARD presented the specimens from a case of *chronic tubercular pleurisy with large effusion*, from A. B., male, 28 years of age; admitted to the Presbyterian Hospital May 23, 1874. Walked to the hospital, and did not complain of much fatigue. The only history gleaned from him was to the effect that he had had what he called an attack of "pneumonia" (undoubtedly pleuro-pneumonia) about three months previously, which detained him in bed for several weeks. His health had been failing for some months previous to this attack, but since that he had been totally unfit for work, although he has not been under a physician's care. On admission, his left thoracic cavity was found full of liquid, but no further examination was made that night. The next day he was seized with violent dyspnoea, and died within less than twenty-four hours from the date of admission. Just before and immediately subsequent to death a large amount (a pint) of thin frothy fluid was discharged from his nose and mouth.

Autopsy, at which time was first seen by Dr. De F. W. In the left pleural cavity were found three and a quarter quarts of serum and pus intermixed with flakes of lymph. The lung was compressed into a mass about the size of two fists, and was firm and dense. Both the parietal and visceral layers of the pleura were greatly thickened, and the former could be easily detached from the inner surface of the ribs without tearing. The entire pleural surface was covered with a dense layer of whitish, tough, semi-organized lymph, with large fringes and folds which hung loose and floated in the liquid, filling the cavity. At one or two points, small, feeble bands were stretched across the space from the surface of the visceral pleura to the parietal layer. The lung, when opened, revealed a large cavity at the apex, filled with pus, and the entire condensed portion was filled with tubercles undergoing various stages of caseous degeneration. No healthy lung-tissue existed. The right lung contained a small cavity at the apex, and the upper and middle lobes were quite thickly studded with miliary tubercles. The whole lung was filled with an effusion of serum, which was undoubtedly the cause of his dyspnoea and sudden death. The heart, liver, kidneys, and other organs were comparatively healthy in their superficial appearances. The operation of tapping had been considered, but the

crippled condition of the left lung was such as to have prevented any expansion even had the pressure been removed.

The PRESIDENT asked as to the cause of this sudden death. In his opinion, it was highly important to note the peculiarities of these cases in which this shocking accident occurs, since the possibility of such a termination constitutes one of the strong arguments in favor of a timely operation.

Dr. J. EWING MEARS exhibited a small portion of the lower end of the *ileum*, removed from a child aged 2 years and 3 months, the cause of whose death was *typhoid fever*. The apparent absence of prodromic symptoms, and the rapidly fatal termination which took place, seem to make the case one of more than ordinary interest.

The case occurred in a family in which the mother had been under treatment for some time for a chronic disease. Attention was first directed to the child on the morning of the 13th inst., and treatment was asked for a condition of purulent ophthalmia of the left eye, which had suddenly developed itself. The associated symptoms of slight heat of skin, increased temperature, and coating of the tongue, were attributed to the local condition, and therefore did not attract particular attention. The statement furnished by the parents was that the child had been in apparent good health until this date,—had engaged in play with his playmates, and shown no signs of impending ill health. There was no diarrhoea, so far as could be ascertained, and tympanites was not present. The child manifested some irritability on being disturbed, obeyed, however, when spoken to, and was perfectly rational. Local treatment was directed to the eye, and a mild purgative ordered; also a febrifuge mixture; milk and beef-essence for a diet.

In the evening the condition of the patient did not appear to be much changed, except that he complained of cephalalgia. The purgative had acted, without producing hypercatharsis. The temperature and circulation were not increased.

At the next visit, on the morning of the 14th, a marked change was observed to have taken place in the condition of the patient. The pulse was 130, the temperature was notably increased, the tongue was dry, and, except the edges, covered with a brownish coating. Delirium was present, though not very active in character. An involuntary evacuation of faeces had occurred, which was of a yellowish color. There was tympanitic distention of the abdomen. The conjunctival inflammation had somewhat subsided. The symptoms continued to increase in severity until evening, when coma and convulsions occurred, in which the child died, shortly after midnight.

Sixteen hours after, an *autopsy* was made by Dr. W. H. Parish, and the following conditions noted. The dependent portions of the body were markedly discolored from hypostatic congestion. Brownish spots of varying sizes and shapes covered the trunk and extremities.

The vessels of the meninges of the brain were engorged, and sections of the cerebrum and medulla oblongata showed great congestion of the contained blood-vessels. The ventricles were empty. The medulla and upper part of the cord were firm; no evidence of softening. The lungs were normal, the heart firm and contracted. The mucous membrane of the stomach was covered by blackish deposit, which was readily removed, showing the surface normal. The liver was not affected. The gall-bladder was much distended. The adjacent intestines were much stained by contact with the gall-bladder. The spleen was enlarged and congested. The mucous membrane of the small intestine exhibited a very marked reddening, which attracted attention at the duodenum, by the contrast

with the inner coat of the stomach. The solitary glands throughout were enlarged, and Peyer's patches showed beginning ulceration. The mesenteric glands were in great numbers enlarged, varying in size from that of a pea to that of an almond. The kidneys and bladder were not examined.

In connection with this case, it is interesting to mention that on the day of the death of this child another member of the family, a girl aged 5, was attacked with typhoid pneumonia, which terminated favorably.

REVIEWS AND BOOK NOTICES.

ELECTRO-THERAPEUTICS. By D. F. LINCOLN, M.D., Physician to the Department of Diseases of the Nervous System, Boston Dispensary. Philadelphia, H. C. Lea, 1874.

When Solomon wrote, "Of making many books there is no end," he probably had in his mind's eye modern electro-therapeutics: if he had not, his prophecy was one of those generalizations which often apply so strikingly to individual cases. Probably the *raison d'être* of many of these books is the hope that they will prove efficient nets in catching practice; and we can see no other reason for the birth of the present brochure. It is a good book in many ways, free from any striking faults, but equally free from anything strikingly new. We do not think it has the charming simplicity and directness of Reynolds's book, but it is much fuller in many ways, and also has the great advantage of having good cuts, which show the various "motor points." To the novice we can commend it as an introduction to the use of practical electricity, and we doubt not that it will succeed in getting a share of the market from its older rivals.

THE MEDICAL REGISTER OF NEW YORK, NEW JERSEY, AND CONNECTICUT, FOR THE YEAR COMMENCING JUNE 1, 1874. New York, William Wood & Co., 1874.

How valuable books of the present kind are to very many persons, our readers know as well as we do. The volume before us is published under the auspices of the New York Medico-Historical Society, and, so far as one living at a distance can judge, its editor, Dr. Alfred E. M. Purdy, has done his work judiciously and thoroughly. In truth, this closely-printed book of nearly 400 pages must represent a very large amount of work on the part of Dr. Purdy, and must be a veritable encyclopædia of important knowledge to those having dealings with the profession in the region over which it has cognizance. We wish the editor would enlarge the scope a little, so as to take in Boston, Philadelphia, and Baltimore, and believe such a venture would be a financial success. Perhaps, however, the General Medical Directory preparing in this city will render this unnecessary.

PHILOSOPHERS AND FOOLS. A Study. By JULIA DUHRING. 12mo, pp. 357. Philadelphia, J. B. Lippincott & Co., 1874.

This collection of essays can scarcely be classed among medical books; but, as the authoress is a sister of one of our most esteemed contributors, and as certain of the chosen topics are subjects closely allied to important medico-social problems, we call the attention of our readers to the brochure. All of the essays are well written and clearly thought out, but we think our readers will probably most enjoy the chapter upon women. A sensible thinking woman's opinion upon that most recondite mass of potentialities and desires ought always to command respect, and when, as in the

present instance, there is freshness both of conception and of putting forth, that respect becomes heightened by the interest excited. Next to the essay upon women, and perhaps even superior to it, as more introspective, is the one entitled "Greater than Sceptres." In it is handled, with a peculiarly feminine touch, the old but ever-fresh story of love.

SELECTIONS.

ALCOHOL.—As most of our readers know, Dr. Carpenter, of London, has been a most staunch advocate of "temperance." But he has been too much for himself, and has furnished Dr. Parkes an account of his own case for publication:

"After having been a water-drinker during all the earlier part of my life, and enjoying a fair measure of health and vigor, I broke down about ten years ago under the pressure of excessive work, and, besides a local disorder, I then suffered from a total loss of appetite and enfeeblement of the digestive power, so that my whole system was undergoing a rapid lowering. My medical friends recommended me powerful tonics, combined with three glasses of sherry daily, and on this regimen I improved even more rapidly than they expected, and was able in a month's time to enjoy a tolerable dinner, gradually reducing the quantity of wine I took with it. They had at first expected that I should be obliged to winter in the south of Europe; but I rallied so fast that this idea was soon abandoned, and I was able to return to my work after a three-months' absence. Ever since that time I have taken a couple of glasses of light claret with my dinner, and this fluid suits me very well. I often reach home very tired, and feeling as if I could eat nothing, and I am certain that without this little 'fillip' I should eat nothing. The question lies, therefore, in such cases, between the use of the slight alcoholic stimulus and the inadequate nutrition of the body, and I cannot myself doubt which is the *least* of what I am willing to admit to be *two evils*."

Upon this Dr. Parkes says, "Coming from such a man, this evidence seems to me indisputable, and, coupled with that derived from watching patients with weak digestions, I think may be called conclusive."

DISEASE IN OUR BOOTS AND SHOES.—Sir James Paget occasionally gives a clinical lecture at St. Bartholomew's Hospital. On the 1st of June he gave one on "Maladies produced by Boots and Shoes," which is very well reported in the *Students' Journal*, and which possesses so much interest that we transcribe the teaching of Sir J. Paget on this important but neglected subject.

Maladies depending on the wearing of too small and badly-fitting boots are very numerous, such as deformities of the toes, bunions, corns, in-growing nails, painful bursæ, etc. In order to study deformities of the toes, said Sir James, you should obtain a good idea of a perfect foot. In a perfect female foot you find—

1. Great width and fulness of instep.
2. Well-marked great toe.
3. Long second toe, projecting a little beyond the great toe.
4. Very small, or in some cases almost suppressed, little toe.

In the male the great toe is not quite so prominent as the second. The feet of all persons cannot be deformed, nor can corns and bunions be produced in every one. It is doubtless owing to their complete reactive nutrition, the repair that takes place in the night being more than enough for the day's waste. This is not impossible when one remembers the complete repair that occurs after great muscular waste, as in

athletes. The troubles then set up in the integuments, fasciæ, and tendons of the toes are rather to be regarded as diseases set up by the pressure and friction of boots.

1. *Mutual compression of the toes.*—Naturally there is a considerable interval between the first and second toes, and in a less degree between the others, so that when the foot bears the weight of the body, each toe is free from contact with its fellow: hence, in wet clay you would receive a separate impression of each. In the deformity, though, which is produced by small boots, the toes are squeezed together, so as to form a transverse arch, the first and second toes then only bearing the weight of the body. Thus there are formed—

1. Soft corns between the toes by their friction on each other.

2. Hard corns on outer side of little toe and inner side of great toe, and projecting points pressed upon.

3. Complete immobility of the toes, except the great one. The natural mobility in civilized nations does not exist now in more than about one person in five hundred.

4. Painful bursæ between metatarsal bones.

5. In extreme cases corns and chafed spots are produced by the squeezing and rubbing together of the pads of the great and little toes.

Kid gloves, though worn continually, never cause bunions, since the kid stretches to the hands; but in the manufacture of boots, especially ladies' boots, unyielding canvas is used to line them, so that the leather is prevented from stretching and showing the true shape and size of the foot. The foot enlarges when bearing the weight of the body, and also towards evening: hence a boot thus made from a measure taken when the foot is suspended in the air, and in the morning, is too small for the foot in the evening. Women's feet are generally measured in the air, but men's when they are standing on them. The high heels in ladies' boots, too, will be always causing them to walk down-hill, however level the path may be, thus driving the foot more and more to the front. In a well-made English boot this is prevented to some extent.

II. *Deflexion of the toes* falls chiefly on the *great toe*, the result of wearing—

1. Boots too narrow in front.

2. Boots (now out of fashion) having the point in a line with the centre of the heel; the big toe, which naturally is in a line with the inner side of the heel, being deflected outwards towards the point.

3. Short boots especially. In them the great toe is brought sharply in contact with the end, and as the tarsus and metatarsus will not yield much, and the metatarso-phalangeal joint will, a deflexion of the great toe takes place outwards, and sometimes downwards. This is the most frequent and worst form. This deflexion of the great toe is the source of great trouble, as bunions occur over the metatarso-phalangeal joint, soft corns on the second, third, and fourth toes, under which it lies, and, worst of all, a total loss of movement in the great toe.

Treatment of the above deformities.—If just beginning, keep the toes apart by pads of plaster. Isinglass plaster upon felt is the best. The pad must be worn day and night. Of course, bad boots must be left off. The treatment by night is even more important than that during the day, for then especially repair goes on, and the least relaxation in the night more than undoes the good done in the day. Sometimes it has been considered necessary to divide tendons; but these do not produce the deformity: they merely adapt themselves to it. If they are divided, the deep-seated fibrous textures should be divided as well. In the worst cases the great toe has to be amputated.

Deformities of the second toe.—It is doubtful whether these deformities are due to the wearing of bad boots,

as sometimes they are hereditary. There are two kinds:

1. The last phalanx may be turned straight downwards, and is then called the hammer-toe. It is found occasionally in the other toes.

2. Extreme flexion of the first phalangeal joint. It is certainly hereditary, for it is frequently found in children who have never worn boots, but it is greatly aggravated by wearing boots, since corns form on projecting parts.

In the old classic statues the second toe projects beyond the first; but that natural type of foot is going out. The great toe seems now to project beyond the second. In people with flat feet this is always the case. Some say that the deformities of the second toe are congenital; but it is probably an early-produced disease of the fibrous textures.

Treatment.—If beginning in a child, you may cure it by applying a wooden splint below, and keeping it bandaged night and day. When deformity is more advanced, divide the flexor tendons, and apply a splint below, or a splint on the dorsum of the foot, arranged with loops. In later life it is impossible to cure the deformity; but amputation should be done at the point of extreme flexion, not at the metatarsal joint.

The third and fourth toes have no special deformities. They only suffer by being lifted up or pushed down.

The little toe sometimes is almost suppressed, from atrophy resulting from pressure.

Boots then may, besides other diseases, cause deformities which lead to the hardening and contraction of the fibrous structures around the joints.—*The Doctor.*

GLEANINGS FROM OUR EXCHANGES.

USE OF THE CATHETER IN ENLARGED PROSTATE (*The New York Medical Journal*, July, 1874).—Dr. W. H. Van Buren does not believe that the occurrence of prostatic urinary obstruction in a man who has passed the prime of life is evidence that he is beginning to "break up," or that there is little use of undertaking measures for his systematic or permanent relief. He has seen too many instances of cessation of all urgent symptoms with arrest of progressive disease by proper surgical treatment to admit that this is the right course. We have no medical remedy whereby enlargement of the prostate may be checked or dissipated, but the results which follow this enlargement when it encroaches upon the outlet of the bladder may be palliated by accomplishing the removal of the urine just as soon as possible after the natural power has given signs of failing. Commencing with the catheter early, it should be persevered in with gentleness and judgment, regularly and systematically, until a tolerance of it is acquired by the patient, and until he has been taught to use it for himself, and to rely upon it entirely for emptying the bladder. The symptoms of prostatic obstruction, and the coincident pathological changes in the urinary organs by which they are explained, might be interrupted at once by any means capable of preventing the increased muscular effort or straining which the mechanical impediment compels the patient to employ each time he attempts to pass water. The reflex nervous action constantly stimulating the bladder to spasm, the consequent dilatation, sacculation, pouching, and muscular hypertrophy of the bladder, the secondary obstruction which grows up at the outlets of the ureters, where they traverse for three-quarters of an inch the thickening walls of the bladder, giving rise to distention of these tubes and threatening invasion of the kidneys, and, sooner or later, retention of urine,

converting the passive congestion at the neck of the bladder into positive inflammation and leaving behind it a suppurating surface within its cavity, attended by symptoms of catarrh, which when once established never again entirely disappear,—all these results could be prevented if the use of the catheter were adopted early and relied upon entirely. The only exception to the relief thus afforded would be in the case of the passive congestion at the neck of the bladder already mentioned, and caused by the pressure of the prostate on the veins of the vesical plexus. Later consequences which might thus be avoided are atony of the bladder, calculus, and uræmic poisoning. If, after having learned to use the catheter once or twice in the twenty-four hours satisfactorily, the patient's calls to urinate in the intervals are still too frequent, or if the act continues to be in any respect imperfectly performed, it is evident that the pathological changes being caused by the obstruction are still progressive, and that to arrest them definitively he must make up his mind to give up all effort to pass his water in the natural way, and work up to the entire substitution of the catheter.

THE ACTION OF PURGATIVE MEDICINES (*The Practitioner*, May and June, 1874).—It is generally believed that most purgatives increase the number of the stools and render them more fluid in a double manner: first, by stimulating the intestine to increased peristaltic action, and, secondly, by inducing a discharge of fluid from its mucous surface. Some purgatives, like aloes, are supposed to act almost entirely in the former way, others, like bitartrate of potassium, in the latter, while others again, like croton oil, are supposed at the same time to increase the flow of fluid and the peristalsis. Several eminent German authors are inclined to deny that there is any increased flow from the intestinal walls, but regard the quickened peristalsis as almost the only cause of purgation, believing that the liquid stools are produced by the contents of the intestine being hurried along and expelled per anum before there has been time for the absorption of their fluid constituents. Dr. T. Lauder Brunton has lately confirmed the results of Moreau and Vulpian, by repeating their experiments, showing the falsity of this latter theory. The abdomen of an animal being opened, four ligatures were tied tightly around the small intestine, a few inches apart from each other, so as to isolate three portions of intestine. A purgative medicine was then injected into the middle part, the intestine was returned into the abdomen, and the wound sewed up. A few hours afterwards the animal was killed, and on examination the middle portion of intestine, into which the purgative had been injected, was found full of fluid, while the portion on each side was comparatively or entirely empty. Dr. Brunton has shown in this way that croton oil, elaterin, gamboge, and sulphate of magnesium, all cause a copious secretion from the intestine.

Purgatives prove useful in many ways. They hurry the food out of the alimentary canal, and thus lessen the injurious effects of over-eating. By expelling irritating substances from the intestine, they arrest diarrhoea and remove headache and other pains caused either by the abdominal irritation or by the absorption of poisonous matters produced by imperfect digestion and decomposition of food. They relieve biliousness by removing bile, and are most efficient aids in the treatment of chronic poisoning by lead, mercury, or other metals. It is probable that pepsin and pancreatic ferment are absorbed from the intestine and circulate in the blood, where the latter assists in the production of animal heat. They are then secreted anew by the stomach and pancreas, and do their work again. Purgatives lessen their quantity as well as that of the bile; they may thus be useful in fevers, but they injure old

and feeble persons, both by diminishing their calorific power and impairing their digestion. They relieve inflammation by lowering the blood-pressure and thus lessening the congestion; and they prove beneficial in dropsies, both by abstracting water from the blood and diminishing congestion in the kidneys.

DEATH FROM RUPTURE OF AN ANEURISM DURING TRACHEOTOMY (*The New York Medical Journal*, May, 1874).—Dr. J. H. Pooley reports the case of a man, æt. 34 years, who suffered from great and increasing dyspnoea, the cause of which was diagnosed to be stenosis of the trachea from pressure on it by a tumor, the character of the latter not being made out. There was also paralysis of the left side of the larynx. Tracheotomy was decided upon and was commenced, but the patient suddenly died while still on the table.

An examination of the body was made soon after death, and revealed the existence of two aneurisms, one of the arch and descending aorta, and one of the arteria innominata: both of these had become converted into solid tumors by the coagulation and solidification of their contents; they were filled with a very firm, laminated fibrin. At the lower and outer part of the innominate aneurism, near the tube of the artery which was atheromatous and softened, there was an irregular triangular rupture, with a valve-like flap of the coats of the vessel, and in the right pleura about three pints of recently-effused blood. This aneurism pressed directly on the lower part of the trachea, diminishing its calibre one-half. The aortic aneurism was twice the size of that of the innominate, and, like it, perfectly consolidated and filled with laminated fibrin of firm consistence; running over its surface, and stretched and flattened, could be seen the recurrent nerve, which was no doubt the cause of the paralysis, dyspnoea, and cough, though the pressure of the other tumor may have had its share; the lungs and heart were healthy; the aorta and other large arteries, so far as examined, were atheromatous.

THE ACTUAL CAUTERY IN UTERINE THERAPEUTICS (*Missouri Clinical Record*, July, 1874).—Dr. M. A. Pallen considers the actual cautery as one of the most powerful adjuvants in gynecological therapeutics.

The lesions for which the actual cautery may be employed are hypertrophy of the uterine fundus and cervix following parturition (sub-involution), nascent metritis (hyperæmia, infiltration, and enlargement with or without follicular erosion of the cervix), chronic metritis with induration and persistent enlargements (areolar hyperplasia), heterologous growths either pronounced or suspected (such as lupus, fungoid, and epithelioma).

In chronic metritis from sub-involution, etc., the derivative effects of the actual cautery are very beneficial.

In acute metritis after disgorgement of the cervical tissue by scarification or leeches, and a corresponding drain upon the uterine vessels by appropriate catharsis, there is no more powerful agent in the maintenance of permanent vascular contraction than the actual cautery, applied several times at intervals of ten or fifteen days. Cellulitis, peritonitis, salpingitis, parapelvometritis, and erysipelas may be classed as contra-indicants to the use of the actual cautery. After detailing the mode of procedure to be employed in appropriate cases, Dr. Pallen says,—

"One rule, almost a *sine qua non*, which I invariably follow after all severe operations upon the pelvic organs, is to bring the patient as rapidly as possible under the influence of quinine as soon as the reactionary stages indicate any increase of temperature." He has learned clinically that cinchonism to a slight degree is fraught with decided benefit.

RISE OF TEMPERATURE AFTER DEATH FROM FRACTURE OF THE CERVICAL SPINE (*The Lancet*, June 27, 1874).—Mr. A. Godfray reports the case of a sailor who fell and struck the nape of his neck with full force against the bulwarks of a ship. He had all the evidence of a fractured spine: priapism, distended bladder, complete paralysis, etc. His skin was hot and perspiring, and about five minutes before his death the temperature began slowly to rise.

Temperature 106°, as taken between the scrotum and groin, almost at the moment of death (11 A.M.). Five minutes after death (11.5), temperature 107°; 12 A.M., temperature 105.3°; 12.30, temperature 105.2°.

Temperature in rectum 109° (12.30), as compared with 105.2° in groin; temperature 108.2°, 1 P.M.; 107°, 1.30 P.M.; 106.2°, 2 P.M.

The possible causes which may serve to explain the extraordinary rise of temperature observed in this case are the following:

1. Contraction of muscles throughout the whole body—*i.e.*, rigor mortis.
2. Contraction of cutaneous capillaries, tending to continuation of circulation in deeper parts, whilst forming a non-conducting blanket generally.
3. Paralysis of the nerve-centre regulating or inhibiting the temperature of the body; cause unknown.

ANAL ULCERATIONS (*New York Medical Journal*, July, 1874).—Drs. Peau and Malassez, in their work entitled *Etudes cliniques sur les Ulcérations anales*, enumerate the following causes and plans of treatment:

Erythema of the anal region may be induced and caused by foul discharge, copious sweating, hemorrhoids, pediculi, pruritus, want of cleanliness, obesity, long walks, badly-fitting and rough clothes. One or more of these conditions may co-exist in the same case. The erosions of the integument result from this erythematous condition, and they may be seated around the margin of the anus, in the sphincteric portion, and in the folds. They have a bright-red surface, ordinarily studded with little whitish points. They exhale an offensive odor, and their presence renders defecation painful. In some cases they become chronic. The treatment consists in carefully drying the parts, and avoiding chafing, and in the application of mild astringent lotions, starch in powder, lycopodium, and subnitrate of bismuth, with the interposition of soft linen. Repose is often very necessary. When internally situated, tampons saturated in glycerole of tannin or other astringent solution are very beneficial. When vaginal discharges, hemorrhoids, or worms exist, attention must be paid to their removal.

DIPHTHERIA (*The British Medical Journal*, May 9, 1874).—At a meeting of the Medical Microscopical Society, Dr. Greenfield read a paper upon "Diphtheria," founded upon the microscopical examination of specimens from five cases. The author stated his belief that the obscurity and doubt which still seemed to exist upon the origin and structure of the diphtheritic false membrane arose, in part, from the confusion in the nomenclature in common use, especially the fact that "croupous" and "diphtheritic" were terms used in different senses, clinically and histologically. An examination of his cases showed in all the larynx and trachea the mucous membrane, and usually the deeper tissues, in a state of more or less intense inflammation of ordinary character; whilst the false membrane consisted, for the most part, of a stratified net-work of a substance giving the reactions of fibrin, in the meshes of which were contained altered epithelial cells. The amount of adhesion to the mucous membrane was various, but in no case did the exudation actually pass into its substance, although in some cases it appeared adherent by fibrinous bands to the papillæ. He stated

his belief that the false membrane consisted in part of a catarrhal process, with modifications in the epithelium, and in part of a true fibrinous exudation.

A SIMPLE METHOD OF REDUCING THE DISLOCATION OF THE FORE-ARM BACKWARDS (*The New York Medical Record*, July 1, 1874).—Dr. Alexander Murray relates a case of the above dislocation which he reduced in the following manner:

He took his position at the outside of the dislocated arm, and placed the palm of his right hand to the palm of the patient's left, dovetailing his fingers between each of those of the latter. In this way he had secured a firm hold to make extension. He then placed his elbow as a fulcrum and for counter-extension on the fore-arm in front and against the lower end of the humerus, and by a steady pressure downwards and backwards, and at the same time flexing the fore-arm towards the shoulder, caused the luxated bones in a few moments to slip into their natural place.

If the injured individual be too weak, or unable to stand erect, he should be seated sideways on a chair, and made to grasp its back firmly with the sound arm, while the surgeon takes his position at the side of the injured limb parallel to the patient.

HYDRATE OF CHLORAL IN NOCTURNAL INCONTINENCE OF URINE.—Dr. Vecchietti Eduardo has successfully treated several cases with this drug. He believes that idiopathic nocturnal incontinence is due to hyperæsthesia of the bladder, and that chloral acts as an anæsthetic of the great sympathetic.

FRECKLES (*The Druggist*, February, 1874).—Powdered nitre, moistened with water and applied to the face night and morning, is said to soon remove all traces of freckles.

MISCELLANY.

THE APOTHECARY'S OATH.—Who is the guardian saint of the apothecaries we do not know; but somebody has disinterred an ancient oath which formerly had to be taken by every French pharmacist. It runs thus:

"I take to witness, before all, God the Creator of the Universe, in three persons, that during the whole of my life I will observe that which follows:

"I will live and die in the Christian faith. I will honor my parents. I will honor the physicians and masters under whom I have studied. I will never say anything that shall be injurious to the seniors of our order, or to others. I will adorn with my best the dignity of the art, and I will not reveal its secrets. I will do nothing imprudently nor through hope of gain. In acute sickness I will not give purgatives without the order of the physician. I will not touch the secret parts, except to apply remedies to them. I will keep the secrets of the patients. I will administer no poison, neither will I allow it to be administered, even to my enemies. I will not give an abortive remedy, even to provoke the expulsion of a fœtus, except upon the order of a physician. I will not alter the prescriptions of physicians. I will never substitute one remedy for another without their knowledge. I will discourage the fatal practice of empirics. I will refuse to no person my legiti-

mate assistance. I will not keep in my pharmacy stale or badly prepared medicaments.

"In making and observing these rules, may God assist me. *Ainsi soit-il!*"

That is not such an antiquated oath but that we should like to see it revived and respected.—*Medical and Surgical Reporter*.

In a late issue, our venerable cotemporary the *Medical and Surgical Reporter* most gallantly takes upon itself the defence of the oppressed sex. Some one, it seems, not having the fear of his wife before his eyes, or, more probably, being an unregenerate bachelor, "has asserted that a woman has never invented any really valuable mechanical device." Our learned editorial brother "rejoices, therefore, to borrow from a contemporary that Mrs. Ella N. Gaillard has recently invented"—a needle.

M. HARDY, one of the Professors of the School of Medicine in Paris, was recently denounced by the *Univers* for classing the confessional among the predisposing causes of insanity, and the students, by way of protest against the clerical party, saluted M. Hardy, on his resuming his course of lectures, with a double round of applause. The *Univers* stigmatizes them as "irreverent sawbones."

THE state of Dr. Hugh Bennett's health is such as to preclude all idea of his spending the winter in Scotland, and he has, therefore, resigned the chair of physiology at the University of Edinburgh. The principal candidates for the chair, according to recent advices, are Dr. Rutherford, of King's College, Dr. Bell Pettigrew, and Dr. McKendrick.

DR. BURDON SANDERSON has been appointed to the chair of anatomy and physiology in the University College, London, recently vacated by the resignation of Dr. Sharpy, who had held it over forty years.

DR. HENRY HARTSHORNE, of this city, has been invited to attend the next meeting of the British Association as the guest of the Association.

BISHOP LINCOLN is reported to have preached at Westminster Abbey a sermon against cremation, because "it would endanger the doctrine of the resurrection"!!

DR. LEMUEL J. DEAL, of this city, has recently been elected to the chair of chemistry in the Missouri Medical College, St. Louis.

NOTES AND QUERIES.

TO THE EDITOR OF THE PHILADELPHIA MEDICAL TIMES:

SIR,—In the number of the *Medical Times* dated July 4 is a letter signed "A Medical Officer," which is, I think, likely to give rise to mistaken views on the part of the profession in relation to the matters of which "A Medical Officer" writes. I cannot but think that the writer of the letter in question is mistaken in several particulars, and especially in thinking that he expresses the views of the medical staff of the army in calling upon the American Medical Association to take action upon the points specified.

As to the first point: I know of no order which gives a line officer authority to decide, when a medical officer is present with his command, whether an enlisted man shall or shall not be allowed to go on the sick list. Nor am I acquainted with any medical officer of the army who would per-

mit such an assumption of his duties, involving, as it would, injustice to the soldier and discredit to his own position, without making a prompt protest to his immediate commanding officer, or, if necessary, to higher authority.

In the only instance in which I have found it necessary to make such a protest, the commanding officer of the post promptly informed a lieutenant who had refused to permit an enlisted man of his company to go to the doctor at sick-call, that he had no right to do so, and in future must not decline to send to the doctor at sick-call any man of his company who reported himself sick.

It is well understood in the army that every officer and enlisted man reporting himself sick has a right to the opinion of a medical officer as to whether he is or is not able to perform his duties, and that this decision is final.

In the company sick-books which have been in use for several years past, the following certificate is printed at the bottom of each page:

"The above cases have been examined by me before being sent to the surgeon.

"NOTE.—To be signed by any commissioned officer of the company."

I have heard company officers argue that the right to decide who shall and who shall not be allowed to go to the doctor is implied in this certificate, but I have never known such a claim to be admitted by a medical officer or sustained by a post commander.

The reason for having the men who report themselves sick examined by a company officer before being sent to the doctor, appears to me to be evident, and the practice to be a good one.

The company officer, having a more intimate acquaintance with the character and habits of his men than the doctor is supposed to have, may give him information which will assist him in forming an opinion as to the nature or cause of the disease from which the man professes to be suffering, or in deciding whether he is malingering. This information may be conveyed in the form of a remark opposite the man's name, or as a message sent by the sergeant who acts as sick-marcher. Thus, the remark may be made, "confirmed malingerer," "drunk yesterday," "old soldier," "reliable man," etc., etc. To a medical officer who has recently joined a command, such information is of great value, as the "dead-beats" are very likely to attempt to impose upon him, and may succeed unless he is well on his guard.

As to the propriety of always assigning medical officers strictly according to their rank, there is certainly room for a difference of opinion. If a medical officer when he arrived in a department were allowed to select any station he preferred among those occupied by his juniors, and the junior thus displaced to oust any one below him on the list, it would lead to a constant change of station, prejudicial to the interests of the service, and involving great inconvenience and pecuniary loss on the part of medical officers. Again, if the medical officers were "by law allowed to claim precedence of posts according to rank," the interests of the service would often suffer, by the more experienced selecting small and unimportant posts because they were in desirable locations, while posts of greater importance, by reason of their large garrisons, or location in the vicinity of hostile Indians, would be left to those who had recently entered the service.

The right of a medical officer to a choice of station according to his rank and previous services is generally recognized by medical directors so far as is consistent with the interests of the service and the rights of his juniors. The present system of changing medical officers from one department to another about once in three years seems to me to be an excellent one, and to be based upon a desire on the part of the Surgeon-General to do justice to all. So far as I have been able to ascertain, it gives general satisfaction to the medical staff of the army.

ASSISTANT-SURGEON.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY, FROM JULY 21 TO JULY 27, 1874, INCLUSIVE.

WRIGHT, J. P., SURGEON.—To report in person to the Commanding-General, Department of the Missouri, for assignment to duty. S. O. 159, A. G. O., July 23, 1874.

PHILLIPS, H. J., ASSISTANT-SURGEON.—Relieved from duty in Department of the Columbia, to proceed to New York City, and on arrival report by letter to the Surgeon-General. S. O. 159, c. s., A. G. O.

CRONKHITE, H. M., ASSISTANT-SURGEON.—Granted leave of absence for sixty days, to take effect no later than September 1, 1874, providing he furnishes a suitable substitute during his absence. S. O. 35, Military Division of the South, July 23, 1874.

CHERBONNIER, A. V., MEDICAL STOREKEEPER.—To report in person to the Surgeon-General of the Army. S. O. 160, A. G. O., July 24, 1874.

SATURDAY, AUGUST 8, 1874.

ORIGINAL COMMUNICATIONS.

THE PATHOLOGY OF CHOLERA INFANTUM.

BY DR. A. NEBINGER.

Read before the Philadelphia County Medical Society, April 8, 1874.

WE need not say that, even at this late day, the nature and the primary lesions of cholera infantum are matters of doubt, therefore of discussion by writers and teachers of nosology and by practitioners of medicine. There are those who contend that cholera infantum is primarily a gastro-enteric malady *per se*, others, that it is a hepatic gastro-enteric disease,—the liver being the organ originally involved, and the gastro-enteric morbid phenomena and lesions the results or secondary effects of the hepatic disturbance. The question being an open one, we propose examining it and making some remarks upon what we consider the nature of the disease and its primary seat of morbid influence.

The anatomical lesions in cholera infantum which present themselves upon a post-mortem examination are such as indicate derangement of the liver, stomach, and bowels. The portal vessels have been found largely congested, and some investigators have reported cases where an enlargement of the liver existed. The gall-bladder has been found containing a large amount of thick, acrid, viscid bile. In some cases the gall-bladder has been found quite empty. Not a single case, as far as we are aware, has been reported by an undoubted investigator, where the gall-bladder was found containing normal bile. The gastric mucous membrane has been found inflamed, ulcerated, softened, and its follicles enlarged. The mucous membrane of the small intestines has revealed inflammation and ulceration; the glands, solitary and acuminate, enlarged; the mucous coat of the colon has evidenced inflammatory softening. Thus, it is seen, we have cholera infantum revealing, post-mortem, extensive derangements of the liver, stomach, and bowels. Here then let the question be asked, is cholera infantum primarily a disease of all the organs and tissues named, or has it its origin in one only? Does it at once present itself as a hepatic gastro-enteric disease, or is it primarily confined to one of these organs or parts, and gradually or rapidly, as may be, spread itself from one to another, until the whole train or series of the morbid conditions which exist in cholera infantum are produced? These questions have been variously, and in some instances curiously, answered by high authorities. Dr. George B. Wood says, "Cholera infantum may be safely inferred to consist essentially in an irritation or inflammation of the alimentary mucous membrane, directed especially to the mucous follicles, and associated with a congested and torpid state of the liver, probably depending upon the same cause."*

Dr. Robley Dunglison, in his article upon cholera infantum (*The Cyclopædia of Pract. Med.*, 1850, vol. i. p. 427), observes, "that the liver is almost always enlarged, and that this has been regarded as the primary affection." Dr. J. F. Meigs, *Pract. Treatise on Diseases of Children*, 1848, p. 297, says, "I am disposed to believe that cholera infantum is a disease of the mucous membrane of the alimentary canal, which, beginning with morbid development of the mucous follicles or crypts, independent of evident inflammation, occasions first super-secretion from these organs, and after a time runs into inflammation and its results, ulceration, softening, and thickening." Dr. Condie, *Diseases of Children*, 1850, p. 234, remarks in reference to cholera infantum, "that comparing the symptoms during the life of the patient with the appearances discovered after death, it would appear to depend in its earlier stages upon hyperæmia of the mucous membrane, with an augmentation of the functions of the muciparous follicles of the alimentary canal." Dr. Dewees regarded "the congestion of the portal vessels and the enlargement of the liver as secondary effects."

It is unnecessary to further quote the various, somewhat discordant, and at best indefinite opinions entertained and put forth by authorities in regard to the nature, primary seat, or starting-point of action of the morbid influences in this very interesting disease.

Before advancing further, we take opportunity to remark that we do not regard the gastro-enteric phenomena of cholera infantum as primary, but secondary conditions, hence that neither the stomach nor the bowels are originally involved.

Observation, reflection, and the results of the treatment to which we have submitted cholera infantum patients, have brought us to the conclusion that exalted solar heat, long continued, acting upon and through the nervous system, upon the liver, is the cause, and that organ the primary seat of disease, from which radiate all the terrible morbid action, etc., which make up the *tout-ensemble* of cholera infantum. Follow, if you please, while we endeavor to present some of the facts, and construct the argument upon which, legitimately, we think, is based the conclusion that the liver is the primary seat of disease in cholera infantum.

1. The portal vessels are largely congested, the liver sometimes enlarged, the gall-bladder contains in some instances a dark, acrid, viscid secretion, in other instances it has been found nearly or quite empty, but the bile when found has always been abnormal.

2. The season when the disease occurs is summer, or in other words in hot and oppressive weather, and the cases are greater or smaller in number, and more or less grave, and the fatality much or little, as the temperature is very exalted or otherwise and continues for long or short periods. July and August are the months which have the more exalted temperature, and when such temperature is most protracted; they are the periods when the bills of mortality of our cities are much increased in their

* *Pract. Med.*, G. B. Wood, 1847, vol. i.

aggregate numerical amounts by the records of the deaths produced by cholera infantum.

3. Hepatic derangements are emphatically the diseases of the tropics and warmer latitudes of the temperate climates. Nearly all the diseases of the tropics, and a large number of those of the hotter latitudes of the temperate zones, involving the alimentary canal, are complicated with hepatic affections. The diarrhœas are not simple diarrhœas consisting of merely an irritation of and a hyper-secretion or effusion from the mucous membrane of the intestines, but are bilious diarrhœas. So of the dysenteries, they are not simply such, but they take upon themselves a bilious type. The converse of all this is true of the enteric diseases of the cold climates. Exalted temperature long prevailing in the tropics is the predisposing and often exciting cause of the peculiar or bilious enteric diseases of those regions. The predisposing and exciting cause being absent in the cold latitudes, the complications of liver disturbances are also absent.

Permit me here to digress and by the way of an episode to remark that in bilious dysentery and in bilious diarrhœa the liver, with but rare exceptions, becomes first involved, the bowels subsequently as a result of the abnormal condition of that organ.

It will not perhaps be denied that congestion of the portal vessels, the pouring into the intestinal tube of acrid bile, may give rise to all the phenomena which present in bilious dysentery and in bilious diarrhœa. Certain it is that it is the experience of many, that all remedies which may be addressed to the bowels for their relief, if we overlook the great importance of relieving the liver and of correcting its secretion, will at best prove but little better than palliatives, whilst if regarding the necessity referred to, such remedies as address themselves specially to the liver, relieving it of its engorgement and normalizing its secretion, be employed, such diseases will speedily yield to treatment.

4. The morbid conditions of inflammation, ulceration and softening of the mucous tissue of the intestinal canal, the enlargement of the glands, solitary and acuminate, are not peculiar to cholera infantum, but are present in fatal cases of enteritis, dysentery, etc. Yet these diseases do not exhibit the ante-mortem phenomena which give to cholera infantum its special, if not peculiar, aspects.

5. Infancy is the period of life when mankind are most prone to attacks of inflammatory and congestive diseases, favored doubtlessly by the greater degree of irritability existing at this period of life in all the organs and tissues. As we have advanced, we have seen that hepatic derangements and particularly bilious complications of enteric affections are the diseases of the tropics, or, in other words, of protracted exalted atmospheric temperature. We have seen that cholera infantum is a disease coincident with the hotter months of summer in this latitude. If the protracted exalted heat of the tropics is the great predisposing and exciting cause of the hepatic diseases and hepatic complications there, may it not be reasonably inferred, that the

protracted exalted temperature of the canicular days here is to the more irritable or susceptible liver of infants, what the heat of the tropics is to the liver of those who are within the range of its influence? Removal from the tropics to cold or cool latitudes by those afflicted with entero-hepatic diseases of a benign type is followed by restoration of the liver and bowels to their normal condition. Removal of cholera infantum patients from the heat-exalted atmosphere of our cities to the cool atmosphere of the country, and particularly to the ocean-side, is followed by a speedy restoration to health. The tropical invalid when in the cold latitudes is no longer subjected to the predisposing and exciting cause of his entero-hepatic disorder, and, without the use of medicines culled from the diversified departments of the *materia medica*, casts off the habiliments of disease, and robes himself in the attractive costume of health. A return of the health-restored tropical invalid to his hot clime is too often followed by a return of his disease. A return to the city during the dog-days of the convalesced cholera infantum patient is followed by a return of the disorder, ending too frequently in death. How wonderful the analogy of these diseases under similar circumstances, springing up under like conditions, relieved, nay, cured, by the same hygienic management! Having causes and effects so remarkably alike in some of these prominent phenomena and habits, to what other safe conclusion can we arrive than that there exists an identity between the organs primarily affected and the cause affecting them? But the pathologist who teaches that cholera infantum is primarily and continuously a disease of the alimentary canal, asks, have we not revealed post-mortem traces of inflammation, ulceration and softening of the mucous coat of the intestines, and inflammation and softening of the mucous tissue of the stomach? To all of which we answer in the affirmative. In turn, we ask, does not a great organ, which in the discharge of its functions is as important as any of those previously named, exhibit undeniable evidence of morbid action? Does not congestion and sometimes enlargement of the liver exist? Does not the gall-bladder contain an acrid or otherwise vitiated secretion, and is it not sometimes entirely free from its peculiar fluid? Has not the total absence of normal bile been the universal post-mortem revelation in cholera infantum? Have all these conditions no legitimate interpretation? Must they be viewed as merely accidental, or incidental, as it may suit the taste, fancy, or prejudice of the pathologist? We are ready to declare that when taken into consideration with all the circumstances, and all the phenomena of the disease in the living and the dead, they stand out in bold relief upon the foreground of the picture, as its most attractive and most interesting features.

If the presence, post-mortem, of lesions in the abstract, without consideration of the phenomena of the disease, which present during the lifetime of the patient, will warrant a conclusion in regard to its nature; why separate, in the disease under consideration, the morbid conditions outside of the lesions of the stomach and bowels, from them, and

consider the disease an enteric, gastric, or gastro-enteric malady? Why not group all the lesions, make a unit of them, and consider the disease a hepatic gastro-enteric disorder, primarily and continuously? If we refuse to do this, by what authority, by what common-sense rule, shall we, after discovering lesions of the liver, stomach, and intestines, close our eyes to the liver lesions, and determine the nature of the disease by the other morbid anatomical conditions? Would it not be wiser to group all the lesions, forming an entirety of them, and thus regard the disease as a hepatic gastro-enteric disorder? In doing this, while we will not determine where the disease commenced, in which tissue or organ it first manifested itself, we shall at least not deduce a conclusion prejudicial to any of the organs involved, and therefore our conclusions will be less liable to beget an injurious or negative treatment. The opinion in a general way is regarded as being correct, that it is largely an impossibility, in most diseases, to determine their nature by a consideration of the morbid conditions which are revealed after death, independent of, and out of association with, the morbid phenomena exhibited during life. Lesions revealed post-mortem and the morbid phenomena presented during life must be studied together, each given its true weight and value to enable the pathologist to solve the problem and to accurately determine the true pathology of most disorders. Hence, to determine the nature of cholera infantum, what organ or organs become primarily diseased, whether the liver, the gastric, the enteric mucous membrane, or all combined, we must examine and hold under due consideration not only the post-mortem exhibitions, but the morbid phenomena presented during life. Let us therefore inquire what are the chief of the living phenomena. Vomiting and purging; the stools sometimes, though seldom, evidence the complete absence of bile, but generally the presence of a vitiated hepatic secretion. As the disease progresses, aqueous or serous matter makes up the major part of the evacuations. In violent attacks there is great frequency of stools, accompanied with rapid emaciation, great exhaustion, and even collapse, giving the disease, under such circumstance, a marked analogy to cholera.

Having called before us some of the living revelations of the disease, we will unite them with the lesions discovered after death, take them as our guides in the exploration which we are about to make, and see to what rational conclusions they will lead us. We have already learned that after death congestion of the liver exists, that the gall-bladder is either empty or contains an acrid secretion. At the very dawn of the disease the discharges from the bowels are free from bile, or if there is any present it is abnormal. So far the morbid phenomena during life and the revelations after death are in accord. Frequently, independent of the presence or absence of abnormal bile, we have large and frequent discharges of serum from the bowels and the stomach, and mucous matter is often present in the stools. As the serum and mucous matter are the results or products of a diseased en-

teric and gastric mucous membrane, the diseased condition of that membrane necessarily preceded the phenomena of which they were the ultimate products. How shall we account for the origin of the diseased condition of the mucous tissue of the stomach and bowels? Thus: having seen as a first revelation during life that the hepatic action was abnormal, we have gained an important stand-point from which to make further observations. Regarding the liver as having its portal vessels congested and this the cause of its functional derangement as exhibited in either the non-secretion or the secretion of abnormal bile, we will endeavor to see what would be the effects of such condition of the liver and a vitiated bile, or the entire suppression of the secretion of that fluid, upon the stomach and bowels. When congestion of the portal vessels which ramify through the liver takes place, there must necessarily follow a damming up behind them of the blood in the channels through which it flows, and, as a sequence, a throwing back of the current upon its source; the capillary rete of the mucous membrane of the stomach and bowels being the source from whence the liver receives its supply of portal blood, when the portal vessels of the liver are congested, as a result of such congestion a congestion of the gastric and enteric mucous membrane takes place by necessity, giving origin to irritation of the mucous follicles, effusion, or hyper-secretion,—the effusion being nothing more or less than an exosmotic action of the venous capillaries of the enteric and gastric mucous membrane. Thus we account for the large and exhausting serous discharges and part of the morbid condition of the mucous membrane of the stomach and bowels, as secondary results of the congestion of the liver.

Simultaneously with the congestion of the mucous membrane of the bowels and the exosmotic action of its venous capillaries, we have acrid bile thrown into the intestinal tube, producing in the highly irritable and very delicate mucous tissue of a babe's bowels follicular enlargement, ulceration and thickening, to say nothing of inflammation, all secondary conditions, resulting from the congestion of the liver. Then we have vomiting, persistent and exhausting. May not this be, is it not indeed, the result of irritation and congestion of the gastric mucous membrane, produced by the acrid secretions of its glands and follicles, arising from the congestion of the gastric capillary rete, produced, as already stated, by congestion of the liver? Add to all this the great probability of morbid influences being transmitted from the bowels, and then say if the account will or will not embrace all that may be necessary to produce the gastric morbid phenomena presented during life, as well as all the lesions which are present after death, in the stomach. Having traced, step by step, the predisposing and exciting cause, the phenomena, the parts involved, and the lesions which make up the totality of this interesting disease, in the regularity, to a certain extent, of their succession, we trust there is good and sufficient cause to consider, certainly for not rejecting hastily, the conclusion that in cholera infantum the liver is primarily diseased, and that

the gastric and enteric disturbances are secondary to, and hence the offspring of, the hepatic congestion, thus indicating that the nature or pathology of the disease consists primarily in congestion of the liver, followed by, and continuous with, and depending upon it, derangement of the bowels and stomach.

The definite fixing of the original or primary seat or starting-point of this disease is all-important, as regards the character of the treatment it should receive from its incipency to its close. It is of great, nay, almost of vital, importance to the little cholera infantum patient, whether the physician shall regard the enteric and gastric mucous coats, the primary and (may we not add?) the only seat of disease, and the nature of the malady, an enteric and gastric irritation only, or that the disturbance of these tissues, although very active, yet secondary to and dependent upon the congestion of the liver. The physician in his treatment will necessarily be influenced by the pathological view which he may adopt in regard to the disease; hence the importance of the adoption of a correct one.

Before closing, we cannot forbear venturing the opinion that it fully accords with the observation of every medical gentleman, who has paid much attention to this disease, that it cannot be considered as presenting a truly favorable and yielding aspect until the stools evidence the presence of normal bile. If the declaration which we have just ventured be true, as we believe it to be, it points with much force to, and is highly suggestive of, the liver being the important and controlling seat or centre of the malady. Do what we may, treat the disease as we please, the fact still remains, if we fail to produce a flow of normal bile our patient remains ill, with perhaps the malady moderated, not cured: the gastric irritability may have subsided, the evacuations from the bowels be less frequent, less copious, less aqueous, but unless we have normalized the hepatic secretion, our patient will remain in a doubtful condition. Normalize the bile: this done, every bad symptom begins to pass away, and convalescence dawns. Such has been our experience, and, comparing notes with our brethren, we have no cause to be dissatisfied with that experience.

ANIMAL LIGATURES.

BY JOS. BERENS, M.D.

IN his very able article on Ligatures, published recently in the *Philadelphia Medical Times*, Dr. J. R. Haynes concludes that there is no better ligature than silk. The following experiments would seem to show a different result. In the experiments of Dr. Haynes there are not a few grounds for fallacy, or, at least, obstacles to correct deductions. Thus, ligatures of different materials were often applied to the same vessel at the same time, and so close together as materially to interfere with any accurate observation of the separate results. Vessels

were invariably chosen so deeply seated as to insure a great disturbance of tissue in reaching them, which, together with the distance of the ligature from the surface, must necessarily have to a great degree impaired the development of symptoms peculiar to the material of the ligature. In many of the experiments, cats were used,—animals which the writer, after over a dozen trials, gave up as altogether unfit for the sort of work in hand, on account of the peculiar nature of their skin, and the strong tendency always existing in them to very great suppuration. Finally, sufficient care was not taken in conducting the experiments to oppose the results derived from the employment of different materials.

In the following experiments these sources of error have been, as far as possible, avoided.

The main points to be decided seem to be, whether any material can be employed for ligatures which will not be more irritating than silk, yet hold the vessel as well, and, in addition, be ultimately absorbed; the object being to obtain in the ligature a body that will be as little as possible foreign to the wound, not only in respect to its irritating qualities proper, but also with regard to the amount of it to be left in contact with the raw surfaces; that is, to get a substance causing so little irritation, and being so readily absorbed, that after securing a vessel the ligature may be cut off close to the knot and the wound closed over it.

With reference to the points involved, three methods of procedure were adopted: 1, setons of the different materials were placed side by side, beneath the skin of dogs. By noting from time to time the effect of these setons in the swelling and general inflammatory symptoms they produced, also the effect of the surrounding tissues upon them, and, finally, by laying open the track in which they lay and observing the condition of affairs within the wound, very effectual comparisons could be drawn in regard to their relative irritating properties, as well as their absorbability.

These experiments were then verified by placing knots of the different materials under the skin. After this, ligatures of the different materials were applied to the arteries of the animals, by which means their qualities in this respect were tested under circumstances very similar to the conditions to which they would be subjected in their employment on man.

The materials experimented with were the imported carbolized gut, prepared on the Lister method, uncarbolized gut, the smallest size guitar-string, peritoneum cut into strips and rolled, as recommended by Dr. Agnew, and beef-tendon dried, split into fine shreds, and twisted. Silk was generally used, also, for the sake of a standard of comparison.

The setons which will be now discussed were, in general, about equal in thickness to three strands of ligature-silk, and were about three inches long. These setons were introduced by means of a long needle, with the production of as little irritation as possible; they were placed side by side, and about an inch and a half apart.

CASE.	TIME.	SILK.	CARBOLIZED GUT.	UNCARBOLIZED GUT.
I.	24 hours.	Inflammatory symptoms.	Slight inflammatory symptoms.	No symptoms.
	48 hours.	Marked welt, and plentiful discharge.	Marked welt; a drop of pus could be squeezed out.	A very slight welt, but no pus.
	3d day.	Unchanged.	Symptoms increased.	No change.
	5th day.	Unchanged.	Much improv'd.	No symptoms.
	12th day.	Opened track, and found much inflammation and excavation.	Symptoms sl't. The seton parted in middle upon slight traction; it had been very nearly absorb'd. Opened, and found slight inflammation.	No symptoms. The seton had been absorbed in centre, and one end had fallen out. Opened, and found track partly healed, and inflammation very slight.
II.	24 hours.	Welt, but no discharge.	Slight welt; no discharge.	Slight welt; no discharge.
	48 hours.	Tolerably well-marked welt, and slight discharge.	Marked welt, and discharge.	Unchanged.
	4th day.	No change.	Welt not so marked, sl't discharge.	A little pus could be pressed out.
	5th day.	No change.	Some improvement.	No welt; no pus.
	10th day.	No change. Open'd track, and found well-marked inflammatory symptoms.	Slight welt; no pus; ends of seton separated on sl't trac'n. Opened, there were few signs of inflammation.	No change; seton still pretty firm. Opened, and found seton reduced to fine thread, with little or no inflammation.

CASE.	TIME.	SILK.	CARBOLIZED GUT.	PERITONEUM.
III.	24 hours.		Symptoms not marked.	No symptoms.
	48 hours.		Moderate welt and discharge.	Small welt, no pus.
	4th day.		Symptoms increased.	Decided welt, and brisk discharge.
	9th day.	A moderate welt, and sl't discharge persisted throughout. On opening, marked inflammatory symptoms were found.	Symp'ms much improved. Opened, and found seton softened, and much reduced in size, track not much inflamed.	No change. Opened; seton not much reduced, inflammatory symptoms well marked.
IV.	24 hours.	Slight welt.	No symptoms.	Slight welt.
	48 hours.	Slight welt and a little pus.	Slight welt and discharge.	Marked welt and free discharge.
	4th day.	Unchanged.	Slight welt and discharge.	No change.
	7th day.	Unchanged.	Slight welt; no discharge.	Symptoms improved.
	10th day.	No change. Opened, and found the track very red and inflamed.	No change; seton separated upon slight traction. Open'd; there was scarcely any sign of inflammation.	Slight welt and discharge; seton still firm. The track was much inflamed and excavated.

CASE.	TIME.	SILK.	UNCARBOLIZED GUT.	TENDON.
V.	24 hours.		No symptoms.	No symptoms.
	48 hours.		Slight welt.	No symptoms except slight welt.
	3d day.		Welt a little more mark'd, slight discharge.	Slight welt, no discharge.
	6th day.		Unchanged.	Unchanged.
	12th day.	The inflammation throughout has been but slightly marked.	No symptoms. Intermediate portion of seton absorbed.	No symptoms. Seton reduced in size; parted on slight traction.

CASE.	TIME.	SILK.	UNCARBOLIZED GUT.	TENDON.
VI.	48 hours.	Slight welt, but marked discharge.	Slight welt, no pus.	No symptoms.
	3d day.	Unchanged.	No change.	No change.
	4th day.	Improved.	Welt almost disappeared.	No symptoms.
	10th day.	Marked welt, and brisk discharge.	Scarcely any welt perceptible. The seton reduced to fine thread which separated very readily on slight traction. On laying open the track, but slight inflammatory symptoms could be discovered.	No symptoms. By exerting considerable force the seton separated. It was flattened and much reduced in size. Laying open the track revealed no signs of inflammation whatever.
		Opened, and found decided inflammation and suppuration.		
VII.	48 hours.	Welt well marked; very little pus.	A slight welt.	No symptoms.
	3d day.	No change.	Moderate welt, and discharge.	Small welt, no pus.
	5th day.	No discharge, but marked welt.	No discharge.	No change.
	10th day.	Discharge and welt. Open'd, the track of seton very much inflamed.	Symptoms very slight. Intermediate portion of seton has been absorbed, and one of the ends fallen out. On opening the track, very slight inflammation could be discovered.	No symptoms. Upon attempting to withdraw the seton it refused to come. Laying open the track revealed the seton buried in the tissue, and apparently adherent, creating not the slightest disturbance.
VIII.	24 hours.	A welt.	Slight welt.	Slight welt.
	48 hours.	Pus and welt.	No change.	No change.
	3d day.	No change.	Welt much diminished.	Welt barely perceptible, but a drop of pus could be pressed out.
	6th day.	Pus flowing freely; the dog's back is wet with it.	Scarcely any swelling.	No swelling, no discharge.
	7th day.	Opened, and found the inflammation marked.	Opened; inflammation exceedingly slight. Seton reduced to one-third its size.	Upon attempting to force the director through the track, great difficulty was experienced. The seton was found flattened, and bound down by bands of tissue thrown over and around it. The track was apparently healed completely, with the seton <i>in situ</i> . Seton not diminished much in size.
IX.	48 hours.	Marked welt, no discharge.	Slight welt.	Slight welt.
	3d day.	A little pus could be squeezed out.	Moderate welt, and discharge.	Well-marked welt, no pus.
	7th day.	No change.	All symptoms have disappeared.	Welt much reduced.
	13th day.	Slight welt, no pus. Opened, and found but slight inflammation.	No change. Opened, and found slightest possible inflammation at one end, where portion of seton still remained, the other part having dropped off.	Nothing to mark the track but the protruding ends of the seton, which was reduced to a few loose shreds. The inflammation was less, if possible, than that in the case of the gut.

A large number of experiments with setons, similar to those the notes of which are given, were performed. The cases quoted have been selected with the view of presenting the average result. The animals used were dogs, the hair being either shaved or trimmed close over the tracks of the setons. Cats were also used to some extent, but, proving unsatisfactory, owing to the peculiar looseness of the skin, were abandoned, and the records of experiments on them were not taken into consideration.

A very superficial examination of these notes will reveal the fact that silk was at least as irritating as any of the materials used. The introduction of it beneath the skin was invariably followed by a distinct welt, which, except in rare instances, was accompanied by a discharge of pus more or less marked. In some cases this discharge was so severe as to drench the animal's back for days, while other materials which lay within an inch or two of the silk were creating little or no trouble. Next to the silk come the carbolized gut and peritoneum; reference to the notes will show that these were very nearly similar in the amount of irritation they produced, especially during the first few days, the symptoms of the gut usually ameliorating very greatly after the fourth or fifth day. This mending of symptoms in connection with the gut after some days was probably due to the fact that by that time whatever carbolic acid had been introduced became absorbed or was washed out by the discharge. The peculiar tendency of the peritoneum to produce inflammation is doubtless dependent upon something in the material itself, as every precaution was taken in procuring the membrane fresh from recently-killed cattle, and in preparing it for use. Unlike the carbolized gut, the peritoneum created disturbance as long as it remained in the wound. Next in order comes the plain gut. In the majority of instances the results were most favorable, very little inflammation being induced as a general thing by its presence, and when there was any it was always marked by a welt much smaller and a discharge much less profuse than usually existed in the case of any of the preceding materials. Occasionally there was nothing to indicate the presence of the seton but the two protruding ends,—not the slightest welt or a drop of pus. If the behavior of the plain gut was satisfactory, that of the tendon was eminently so. If the introduction of the plain gut was occasionally followed by no symptoms, that of the tendon was very rarely followed by any signs of inflammation. Indeed, in many cases the protruding ends appeared like large white hairs growing from the dogs' backs, so little disturbance did they create and so closely did the orifices of the track adhere to the seton. In Case VIII., the seton seemed actually to have contracted adhesions and to have become a part of the tissues in which it was buried. The same thing occurred in another case, not quoted.

As to the comparative absorbability, the relations are somewhat altered. In this respect reference to the notes will show that the plain gut stands at the head, then comes the carbolized gut, and after these the peritoneum and tendon. The average length of

time—computed from the experiments made, and six special ones—required for the absorption of a seton of the ordinary size, is, approximately, for the plain gut eleven days, for the tendon sixteen days. Of the experiments where knots of the different materials were placed beneath the skin, a few cases will now be given. These knots were all deposited without making any incision. The knot was made and attached to a loop of silk so arranged as to be easily withdrawn; a broad needle was then employed, by means of which the silk was passed under the skin, and the knot was then pulled into the desired position and the silk removed. By thus avoiding an incision directly over the position of the knots, a more correct estimate could be made of symptoms, the swelling, pus, etc., produced.

Case I.—Two triple knots, one of plain the other of carbolized gut, were introduced beneath the skin of a dog. In four days there was a swelling the size of a walnut over the position of the carbolized gut. When this was opened on the fifth day, the knot was discharged softened but not much reduced. The amount of pus was large. The plain gut produced a little swelling, which subsided, however, in about a week; on the seventieth day no trace of it could be found after careful search.

Case II.—Two knots as before. For the first two days there was considerable swelling on the part of both; the swelling over the plain gut had disappeared upon the fourth day, that over the carbolized gut at the end of a week. Both lay after this, creating no disturbance, for two weeks; when searched for at the end of this time they were found very much reduced in size.

Case III.—Triple knots of plain and carbolized gut, peritoneum, tendon, and silk, were placed an inch apart in a dog's back. At the end of the third day the silk, peritoneum, and carbolized gut were exciting considerable inflammation, the other two lying quiet; upon the fourth day the silk was discharged by a touch of the knife from a small abscess it had formed; the peritoneum and carbolized gut were found buried beneath the skin, with evident signs of pus; the plain gut and tendon were found lying inert, except that they were surrounded by a small quantity of lymph.

Case IV.—Two triple knots, one of plain silk, the other of silk saturated in a carbolic solution taken from a bottle of the imported gut ligatures. At the end of twenty-four hours the silk had created but slight disturbance, while the site of the carbolized silk was marked by great swelling and a high degree of inflammation, which culminated in a well-marked abscess on the fourth day, at which time there was only well-marked swelling over the plain silk. On cutting down upon the knots, the plain silk was found buried in a moderate amount of pus which equalled in amount about one-quarter of that in which floated the carbolized knot.

It will be seen that these results verify very strikingly those obtained from the setons,—the silk still presenting its irritating features, the carbolized gut and peritoneum standing next in this respect, the plain gut and tendon manifesting the fewest objectionable points. In addition, Case IV. demonstrates very clearly the irritation which carbolic acid will originate in the tissues.

In the next series the experiments were directed to the ligation of arteries. The ligatures employed were generally about the size of doubled silk; when silk was used it was doubled. The ends of the silk

were cut off close to the knot. The animals used were dogs.

Case I.—The femorals of a large dog were secured with carbolized gut ligatures. Two days after, there was considerable discharge, but only ordinary swelling, both of which subsided in about a week. The right side healed on the eleventh day, the left on the twelfth day. Search being made for the ligatures two weeks after, nothing could be found of them except a few shreds surrounding one of the arteries.

Case II.—Right femoral with carbolized gut, the left with silk. Both exhibited signs of inflammation in a marked degree; this subsided, however, in a week, and the wounds were both healed by the thirteenth day. At the end of the third week the silk was found to have severed the artery, and lay in a cyst that looked like a lymphatic gland. The gut could not be found; the artery was obliterated, though the external coat was not severed.

Case III.—Right femoral with carbolized gut, the left with silk. The wound on right side healed in ten days, that upon the left side requiring eleven days. On the fifteenth day the silk was found close to the surface and buried in pus. The vessel upon the right side was found severed, with nothing left of the ligature but the rounded knot. This was, apparently, causing very little inflammation.

Case IV.—The right femoral of a large dog with *uncarbolized* gut, the left with silk. The wound over the gut healed in seven days, that over the silk requiring eleven days. In three weeks the wounds were reopened. No trace of the gut could be found; the artery was obliterated, but the external coat intact. The silk was found imbedded in pus.

Case V.—The same experiment repeated. The results were very similar, excepting that at the end of two weeks the gut was found almost unchanged in size, though much softened.

Case VI.—In this case the wound over the gut healed in eight days, that over the silk in nine days. In neither case was there much swelling. At the end of four weeks the silk was found lying harmlessly upon the artery, which was severed. No trace of the gut; the artery had been severed.

Case VII.—A large dog. The right femoral with *carbolized* gut, the left with *uncarbolized* gut. The right side showed much swelling and discharge, and did not heal for twelve days. On the left side the swelling was by no means so great, nor the discharge so profuse. It healed in nine days. Upon opening at the end of two weeks, nothing could be found of either ligature but the knots, rounded and smooth, and apparently producing little inflammation, if any.

Case VIII.—Right femoral with tendon, left with silk. The right side healed in eight days, the left requiring twelve. At the end of two weeks the wounds were opened. The tendon ligature was found reduced to a pulp, lying between the cut ends of the artery, with no bad symptoms. The silk was found in a small abscess.

Case IX.—The two femorals of a medium-sized dog secured with tendon ligatures. Perfect healing took place in a week. On opening the wounds three weeks after, the arteries were found obliterated, with external coats intact. Nothing left of the ligatures but two shining knots the size of a pin's head.

Case X.—Secured the right femoral of medium-sized dog with silk, left femoral with tendon. Six days afterwards, the wound upon the left side was completely healed, and presented but moderate swelling, while that upon the right side was still open, much swollen, and discharging freely. On searching for the ligatures, the silk was not to be found, having probably been discharged, the vessel having been completely cut

through; the tendon was found much softened, but still surrounding the artery, which, though completely occluded, was not divided.

Case XI.—Ligated right femoral with silk, the left with tendon. For four days the left side wore an unhealthy aspect, while the right side looked well. At the end of a week there was no difference to be observed between the two sides. Both wounds were completely healed on the ninth day. On the tenth day a small lump was felt over the site of the silk ligature; this upon cutting down was found to be a large cyst, which when opened proved to contain the ligature, together with a quantity of pus. Search was made for the tendon ligature upon the thirteenth day; nothing was found of it; the vessel was reduced to a fibrous cord.

Case XII.—The two femorals of a medium-sized dog secured with tendon ligatures equal in size to *fourteen strands* of silk. Both wounds were healed perfectly upon the *tenth day*. The vessels at the end of two weeks were found obliterated; external coats not cut; on the arteries lay the knots of the ligatures, looking like pearls, so smooth and shining were they. They were reduced half in size.

Case XIII.—Right femoral of a large dog tied with a single strand of silk, the left femoral with a fine thread of tendon somewhat smaller than the silk. The wound over the tendon was healed perfectly on the sixth day, that over the silk upon the eighth day. At the end of twelve days the silk was found lying loosely between the severed ends of the artery, causing no trouble. No trace could be found of the tendon ligature upon the left side. The artery was obliterated, though the external coat was still intact. The arteries in this case were quite as large as the femorals in man.

The next material employed was peritoneum, with, however, unsatisfactory results. Three femorals were secured by ligatures of peritoneum, and none of the incisions did remarkably well: one was healed completely on the ninth day, the other two remained open, discharging freely, one for twelve days, the other for two weeks.

Great care has been taken in selecting the cases reported, especially with reference to the position of the vessel and the manner in which it was tied. Carotids and brachials have been excluded, owing to the great disturbance of tissues necessary in securing them; all femorals, also, have been excluded, when there was any bungling in their ligation. The cases quoted may be regarded, therefore, as presenting a fair record of the results obtained, inasmuch as the vessels are all of the same kind, and the operations for securing them very nearly equal in point of disorganization of tissue occasioned by them. Further, the ligatures being deposited so near the surface, their effects could be very readily studied. A review of the notes will show results which might have been anticipated from those obtained from the setons. The silk and peritoneum generally took the lead in the inflammatory symptoms engendered, the attendant swelling and discharge being usually great, and the time required for the healing process somewhat prolonged, when compared with that of the other materials. The carbolized gut comes next in order, but there was no marked difference between it and the preceding ones, there being usually about the same amount of trouble after a ligature of it was deposited; the time of healing, however, was a trifle less,—not quite a day, all cases in which it was used

being considered. After these follow the plain gut and tendon, between which and the foregoing there was a well-defined line of demarcation. The behaviour of the plain gut was very satisfactory, proving it to be readily capable of absorption and but slightly provocative of inflammation, in which respect, however, it was scarcely equal to the tendon, owing perhaps to the processes to which it is subjected in manufacture.* The tendon proved in a marked degree non-irritating; as, for example, in Case XII., where a large bulky ligature, double-knotted round a vessel about one-fifth its size, produced little or no trouble comparatively, and permitted perfect healing of the wound in ten days. The tendon, on the other hand, is by no means so absorbable as the gut.

Approximately, the time required for the complete healing of the wound computed from all the experiments was, for the silk and peritoneum, a little less than eleven days; for the carbolized gut, a little more than ten days; for the plain gut and tendon, between eight and nine days.

The three sets of experiments, taken together, show a result undeniably favorable to the plain gut and tendon.

Comparing the advantages of these two, we find the gut very non-irritating and rapidly absorbable, but making a ligature that scarcely grasps the vessel as firmly as silk, and with rather a bulky knot; on the other hand, the tendon is non-irritating to the last degree, not rapidly absorbable, capable if need be of being made up into threads of almost any degree of fineness, which grasp the vessel quite as well as silk, and at the same time make an excellent small knot. The extreme non-irritating properties of the tendon, coupled with its capacity for fine division, would render its slow absorption of decided advantage, since a vessel could be secured with a strand of it so fine as to produce no irritation, and yet there would sufficient time elapse before its disappearance to render any danger from secondary hemorrhage as remote as in the employment of silk, by which the vessel is usually severed in the course of a very few days. As to the ability of a fine strand to control even a large vessel, attention is called to Case XIII. Here a vessel as large as the femoral artery in man was secured with a ligature so fine as to pass readily through an ordinary cambric-needle. The result, as may be seen, was not in the least prejudicial. Thus it will be seen that the tendon ligature fulfils all the requirements set down at the beginning of this paper for a substitute for the material now in use. It is certainly not more irritating than silk, holds the vessel quite as well, and, in addition, is beyond all doubt ultimately absorbable, so that a ligature of it may be cut off close to the knot and left in the wound. These qualities would render it of great value in amputations. A fine ligature of this kind, applied to the many small vessels that spring after the operation, would certainly have some advantage over

the large strands of silk applied now to every vessel that bleeds, however small. At the worst, the ligatures would give no more trouble than the shreds of connective tissue and the like, more or less of which are always covered in by the flaps. In ligations in continuity, also, the tendon ligature would be of value, having all the advantages of silk and lacking many of its objectionable features.

TRANSLATIONS.

BUCCAL PSORIASIS.—Dr. Debove contributes to the *Archives Générales*, April, 1874, p. 433, a memoir on this affection, which is not by any means an uncommon one in Paris, though infrequent in this country. Dr. D. does not consider the disease identical with psoriasis as usually found upon the skin, though he retains the name, as more descriptive than that of ichthyosis given by English authors. The appearance of the disease is as follows. It presents itself at first in the form of isolated patches so small as to pass unnoticed. These gradually enlarge, however, and assume an opaline transparent appearance. The epidermic layer of the tongue grows thinner and allows the mucous layer to become apparent; gradually the patch becomes opaque. If these changed portions of the surface of the tongue are now examined with a lens, the papillæ are seen to be enlarged and frequently massed together with epithelial collections.

The usual form of the eruption is that of a V-shaped median patch, situated at the junction of the middle and anterior third of the dorsum linguæ: it may spread, however, over the whole upper surface, and occasionally to a less degree over the inferior parts. When the disease is well developed, the surface of the tongue feels hard and resistant, and occasionally this induration is so marked over certain circumscribed portions as to embarrass the diagnosis materially. A frequent concomitant or sequel to psoriasis in this locality is cancrroid.

As to the diagnosis, it is, M. Debove thinks, not difficult. Should the tongue have been irritated by applications, it may be mistaken for eczema. In this case, careful observation, without treatment, will show the characteristic patches taking once more the place of the artificially-created ulcerations. From indurated chancre the eruption is to be distinguished by the much less marked character of the induration, and by its not being accompanied by those glandular enlargements usually found in connection with lingual chancre. Mucous patches are decidedly different in their appearance from buccal psoriasis. Their surface is covered with the tenacious products of secretion, which, while they have a similar opaline appearance, yet when the secretion is scraped off look quite unlike the epithelial covering of the psoriatic patches.

As regards treatment, M. Debove directs total disuse of tobacco in any form, which he regards as having a certain influence towards the development of cancrroid upon the psoriasis. Besides this, he advises alkaline washes and the spray of alkaline mineral waters, as well as their internal use. A. V. H.

ANÆSTHESIA BY ELASTIC COMPRESSION.—M. Laborde reports in the *Progrès Médical*, May 30, the results of some experiments made by himself in the production of anæsthesia by Esmarch's bandage. The experiments were made by applying the bandage in the usual way on a dog's leg, when it was found that anæsthesia sufficient to permit of slight operations lasted for some two to three days.

* In making "catgut," the intestines of sheep are used. They are soaked for a considerable time in water, freed from fatty matter, etc., then treated with caustic potash, drawn through perforated iron plates, and subjected to the fumes of sulphur.

PHILADELPHIA MEDICAL TIMES.

A WEEKLY JOURNAL OF

MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY

J. B. LIPPINCOTT & CO.,

715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, AUGUST 8, 1874.

EDITORIAL.

THE AMERICAN MEDICAL ASSOCIATION.

SOME time since, we had occasion to call the attention of our readers to the curious agreement in sentiment and language between an editorial in the *Chicago Medical Examiner* and one which had appeared the week before in this journal. It will be remembered that no charge of plagiarism was made, although the literal identity of whole paragraphs was complete; and, as our Western confrère took no notice whatever of our second editorial, we concluded that he was not in the habit of reading the *Times*. We are happy to be able to inform our readers that he does now read the *Times*, albeit he writes in no friendly mood and seems sore about something, for in his editorial of July 15 is a long extract from one of our editorials,—this time in quotation-marks.

What if our Chicago brother does contrast his own "liberal and earnest mind, accustomed to work manfully, striving to make the world better," with the "Pecksniff" who wields the editorial pen of the *Times*? What if he does abuse the workman, since he praises the work? Soberly, he writes, "The *Times* is a most valuable journal." Strange, with Pecksniff at its head! We would not, however, have noticed the undignified and feeble personalities which the editor of the *Examiner* has indulged in had we not wanted to say a word about our last editorial upon the American Medical Association,—the alleged cause of his ire. We fear that we have been understood in some quarters as speak-

ing contemptuously of Western physicians, and, in the language of a correspondent, of "stirring up sectional feelings." Nothing, however, was further from our intention. We said, and still maintain, that at the late meeting of the Association only a portion of the profession was represented, and in stating the importance of that portion, it may be, we put our case too strongly. What we wanted to emphasize was—first, the great necessity of the Association being universal in its character; secondly, the fact that at the late meeting the whole profession was not represented. The West is an immense territory, many portions of it even now thickly settled, and all of it destined to be so. Human nature is of very like quality in all parts of our country, and we firmly believe that there are just as good men in the North as in the South, in the East as in the West, in the South as in the North, in the West as in the East. This fact, however, when taken in conjunction with the enormous territory over which the profession in this country is spread, makes it of the more importance that the meetings of the Association should be held in rotation, and that all other measures conducive to making the Association a common point of fusion, a general bond of union between the most widely separated districts, should be taken. In our opinion, this latter function is paramount in importance, and if the American Medical Association fails in this it fails in everything. If space were plentiful, in order to show the justness of our assertion in regard to the late meeting we could cite the names of twenty prominent Eastern medical men who were not there to where our Western brother cites one that was there; but our readers can do this for themselves.

CORRESPONDENCE.

TO THE EDITOR OF THE PHILADELPHIA MEDICAL TIMES:

SIR,—My attention has just been drawn to a review of my book on "Hay Fever," which appeared in your issue of the 15th of November, 1873. With your permission, I wish to be allowed to correct one or two statements made by your reviewer, and to make a few observations on the subject of your American autumnal catarrh.

Your reviewer, in speaking of my experiments, says I found "the intensity of the catarrhal symptoms to correspond closely with the amount of pollen found floating in the atmosphere, as demonstrated by the microscope, and that both reached their highest development in the vicinity of grass-fields during the time of hay-making." The former part of this statement is quite correct, but the latter does not express exactly

what I intended to say in my remarks on this part of the subject. As a matter of fact, hay fever does not depend upon hay-making. The disease generally reaches its highest point of intensity before hay-making begins in England, and declines rapidly as soon as this becomes general. The malady would show itself just the same if no grass were to be cut and made into hay, as it does now each season with this process going on. The development of the specific symptoms entirely depends upon the formation and distribution of pollen during the flowering period; and if this latter process is allowed to complete itself before the grass is cut, no hay fever will be produced by its being made into hay.

Your reviewer also represents me as holding the opinion that hay-fever patients often belong to a gouty family. I may, in an indirect manner, have conveyed this impression in my book, but I am not aware of having done so, and so far as I have been able to inquire into this matter I have not found that those who suffer from hay fever are more liable to gout than those who do not.

At the time my volume went to press I had not seen or heard of Dr. Wyman's book on "Autumnal Catarrh." I have, however, since then read it carefully, and have been much interested with the cases he has collected, and with the numerous facts he gives in connection with these; but, contrary to what your reviewer says would be the case, my reading it has not altered my views on the cause of hay fever, but has helped very much to strengthen the opinions I previously held. So far as I could gather from his book, Dr. Wyman had, when he wrote, no idea of the real nature of the cause of either hay fever or autumnal catarrh, and from a correspondence I had with him since he read my book (whilst over in England) I judge that he believes the cause of the latter disease to be "still a mystery." Our "June cold" or "summer catarrh" (hay fever) is undoubtedly due to the pollen of grass; and after a careful perusal of Dr. Wyman's book I am convinced that American autumnal catarrh and English hay fever are one and the same disease and due to the same cause, —namely, pollen; the one to the pollen of grass, and the other to the pollen of Indian corn, which latter, according to Dr. W.'s book, flowers just at the time your autumnal catarrh is most prevalent.

A few well-conducted experiments tried on the same plan as some of those described in my book would go far to settle this question; and if some of your physicians or laymen who are affected with this disorder will devote themselves to the work for a single season, I have very little doubt that the facts gathered in your own country will be found to support the conclusions I have arrived at by the experiments I have gone through in England. Hoping that some one will be found who is able and willing to devote himself to this inquiry,

I remain, sir,

Yours respectfully,

CHARLES HARRISON BLACKLEY, M.D., M.R.C.S.

STRATFORD ROAD, MANCHESTER, ENGLAND, July 15, 1874.

TO THE EDITOR OF THE PHILADELPHIA MEDICAL TIMES:

I OBSERVED in your issue of July 11, 1874, an article written by Dr. E. P. Bernardy, in which he claimed the honor of being the first American physician to recognize the value of the hydrate of chloral as a therapeutic agent in the treatment of puerperal eclampsia. In a recent number, July 25, I see that Dr. William B. Atkinson disputes the claim of Dr. Bernardy, and assumes that to himself (Dr. B.) belongs the credit. He claims that he used the remedy in question in a case of puerperal convulsions as early as October 26, 1871. I now propose to dispute the claim of my friend Dr. Atkinson, and endeavor to establish priority for Dr. Isaac S. Eshleman. I am thoroughly convinced that Dr. Eshleman was among the first, if indeed he was not the first, of our practitioners to use the new remedy. I know that at a meeting of the Northern Medical Society, in the winter of 1869-70, chloral was the topic of discussion. One after another spoke upon the subject: the great majority not having even granted it a trial, Dr. E. was the only person present who could say anything in its favor. He mentioned at that time that he had used it successfully in cerebro-spinal meningitis and tetanus, and said he believed it applicable to all forms of convulsions.

In order to show how early he had the audacity to use it, I am tempted to mention an incident. He was giving it in a case of convulsions, consequent, probably, upon chronic softening of the brain. In his absence, a brother-physician called to see the case, and horrified the family by saying that chloral was a remedy he had never used, and that all he knew about it was that "scientists had used it in experimenting upon cats and dogs."

On the first day of November, 1870, the doctor was called to see Mrs. S., residing on Wallace Street, who was laboring under puerperal convulsions of the most violent type. He gave her chloral in large doses, and the convulsions were soon under control. I should add that in this case he also resorted to venesection. You will bear me out in the statement, Mr. Editor, that this case occurred almost one year prior to the case mentioned by Dr. Atkinson.

Again, on the 10th of March, 1871, he was summoned at midnight to see Mrs. K., residing on Ridge Avenue. She had been all night in the hands of a homœopathic practitioner. The convulsions were frightful in the extreme. The doctor immediately ordered chloral, and tried to bleed her, but no blood flowed. The chloral was administered quite freely, and as soon as she came under its influence the convulsions ceased, and she made a very satisfactory recovery. She took about one hundred and twenty grains in twelve hours.

This second case was at least eight months prior to Dr. A.'s case. Since this time the doctor has used it with the best possible results in numerous cases of puerperal eclampsia, and has never failed to add his testimony to its efficacy in convulsions, no matter how caused. He has been particularly fortunate with it in the convulsions of quite young children. In cases of

cerebro-spinal meningitis and tetanus it has been almost invaluable.

Yours, etc.,

EMORY ESHLEMAN, M.D.

1333 GIRARD AVENUE.

PROCEEDINGS OF SOCIETIES.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

A CONVERSATIONAL meeting was held April 8, 1874, at 8 o'clock P.M.

The PRESIDENT, DR. W. L. ATLEE, in the chair.

Dr. W. B. ATKINSON stated that he had recently delivered a child at full time whose left arm terminated about one and a half inches below the elbow. It did not present the appearance of having been amputated in utero; but there were two or three processes at the extremity, evidently rudimentary fingers. No cause could be assigned, save that the mother at the third month was frightened by lightning and grasped her left arm convulsively just below the elbow. Last spring, in one of his cases delivered during his absence, the child was hideously deformed, having but one nostril, the palate cleft from the nose completely through, and the eyes placed widely apart. In this instance the father was somewhat similarly deformed. This was her second child, the first one being also deformed, but not to so great an extent. He alluded to a case recently published, where the mother had marked her child with a toad on the back.

He could not offer any theory as to the cause of these deformities. If the sight of a deformity, etc., could produce it, then every woman in a certain part of this city ought to give birth to monsters, as there has lived for many years a man with the well-known fire-mark covering the whole face. This man is an object of great aversion to the females of that section, yet he (Dr. A.) had, although largely engaged in obstetrics in that section, never yet seen anything approaching it. He also alluded to an infant which, during the illness of an older child, had been neglected, where it was found that a worsted thread from its sock had become wound around the small toe, and had cut completely down to the bone. This was an illustration of the effect of elastic bands, as now proposed abroad for amputations, etc.

Dr. W. L. ATLEE stated that in his early professional life, while practising in the village of Mount Joy, Lancaster County, Pa., he attended a farmer's wife in confinement, who, immediately on the birth of the child, asked if it had a hare-lip. The child *had a hare-lip*; but the question having been evaded, she peremptorily repeated it, and said that she knew it was so deformed. She accounted for it by saying that in the early period of her pregnancy she had attended a public sale at a neighboring farm-house, where a number of people had assembled, and among them was a man with a hare-lip, who was continually obtruding himself upon her. His deformity made a deep impression upon her, and continually haunted her up to the period of parturition.

Soon after, a converse occurrence took place: a young married lady, three or four months pregnant, was much frightened by a fire which threatened to burn down her parents' house. In her distress, she bewailingly covered her face with her hands. The old women around her tore her hands from her face, and said, "You will mark your child." A strong impres-

sion was made upon her mind, and, as in the other instance, she could not divest herself of the idea that her child would have a "fire-mark" on its face. Such, however, was not the result.

In reference to the agency of the umbilical cord in producing deformities, and even death, of the fœtus, Dr. Atlee mentioned a singular case of suicide by a fœtus in utero.

A lady was taken in labor within a week of her full period of gestation, but had felt no motion for three weeks before. It was a foot-presentation, with the back of the child to the front of the mother. The child was dead and putrid, and the liquor amnii was of a dirty dark color. On investigating the cause of death, a very tight knot, which totally impeded the circulation, was found in the cord about nine inches from the body of the child.

Dr. F. J. BUCK mentioned a case at the *Free Excursions* last summer, where both legs of a child terminated below the knee-joint. The mother ascribed it to an impression made by the beggar on Chestnut Street, with whom all were familiar.

Dr. STUBBS mentioned the case of a woman who put her hand in a rag-bag during pregnancy, and a mouse ran up her arm. She was greatly startled at the time, and when her child was born there was shown a line resembling mouse-fur running up the arm.

Dr. A. NEBINGER then read a paper on "The Pathology of Cholera Infantum."

Dr. ATLEE remarked on the paper of the lecturer that there was a great difference between good arguments upon false data and those upon correct data. The reasoning of the lecturer was plausible, but in his opinion it was based upon erroneous premises. In most cases of cholera infantum, of choleroïd, diarrhœa, and dysentery, he believed that the affection of the liver was secondary, and that if the incipient stages of these diseases were properly treated, very little or no hepatic trouble would be manifested, and consequently no necessity of directing any special remedy to the liver. The portal circulatory system is so constituted that it takes its origin in the chylopoetic viscera and the alimentary canal, conveys the blood thence to the liver, and again ramifies throughout the structure of the latter organ. Consequently, any morbid action developed in the mucous membrane of the alimentary passages may more or less affect the condition of the blood in the vena porta; and as the current is from the intestines to the liver, the latter may suffer from the presence of this impure fluid. The primary irritation being in the *primæ viæ*, the secondary effects are manifested in the liver. Now, the first indication in all these derangements of the bowels is to get rid of the cause of the intestinal irritation; and if this be accomplished at the very earliest period, there will be very little danger of hepatic trouble. The safest and most successful plan, according to Dr. A.'s experience in the treatment of these and other intestinal diseases, is, immediately on their accession, to order, for an adult, a dose of castor-oil (fʒi) and laudanum (gtt. xv to xx), to remove the irritating contents as well as the mucous irritation, and, if need be, afterwards to give sulphate of soda (gr. viij) and opium (gr. ½) every two hours, with an additional dose every time the bowels are disturbed, and to continue this treatment until natural stools are induced. If this be done, in ninety-nine cases out of a hundred not a particle of medicine need be prescribed for the liver, as its action will be normal. If, however, the irritating ingesta be locked up in the bowels by astringents, cholera-mixtures, etc., the irritation will be aggravated and prolonged until the portal circulation will become poisoned, and the very results so well described by the lecturer will be developed, and his diagnosis confirmed

by post-mortem examination. The therapeutic success of such a plan of treatment illustrates infinitely better the pathology of these diseases than do any autopsical examinations, and at the same time saves the trouble of verifying our diagnosis by the latter means.

Dr. A. remarked that there were more potent causes than heat operating in large cities to originate and maintain cholera infantum. No doubt the high thermometric condition of the atmosphere had more or less influence; but when we go into our markets, and see the character of our milk and other articles of food by which our children are fed, we find a more efficient cause of intestinal disturbance. And when these sick children are sent into the country, it is not so much a diminution of temperature (which does not necessarily follow) as it is a change in the purity and freshness of their food that operates towards their recovery.

Dr. A. said that the poor liver had been charged with committing a great many sins. He thought it had been too much slandered. He had endeavored to explain his views in reference to the abnormal condition of the liver,—that it was merely a secondary affection, resulting from a neglected primary irritation in the intestinal canal. He would ask the lecturer to explain how heat operated to produce the condition of the liver so graphically described by him.

Dr. NEBINGER said that in his opening remarks upon the disease under consideration he took opportunity to observe that the pathology of cholera infantum was an open question. The remarks of those who had followed him in the discussion being adverse to the proposition put forth, that the liver is the starting-point of the disease, must be regarded as an indorsement of his declaration that the pathology of cholera infantum is yet an unsettled question. He said he was not surprised that his views had met with adverse strictures: indeed, it was precisely that which he had expected. He felt that to-night, as was his habit in the Society upon other occasions not very remote, his flint would strike the steel of his fellow-members, and from the blow heat and light would be evolved. He had not been disappointed.

Dr. Atlee in his remarks said that the first indication in cholera infantum is to get rid of the cause of the irritation of the intestinal tube, and if this be done at the very earliest period there will be very little danger of liver-trouble. This declaration of the doctor's is at best a little vague and unsatisfactory, and not reconcilable with the conditions which must have been met with in almost every, yea, he could add, in every instance of cholera infantum. The remarks of the doctor are, virtually, that if the bowels be promptly freed of their contents,—that is, of that which they contained at the time the attack of cholera infantum set up,—the freeing of the bowels would not only prevent the involvement of the liver, but would give health to the child. Certainly the doctor has forgotten that, in the vast majority of instances, when the physician has been summoned to treat cholera infantum, long before his arrival at the couch of the patient, without the action of any medicine, the bowels have been freely emptied, all irritating ingesta removed, and there is pouring out from the bowels but little if anything else than serum and mucus; yet, notwithstanding this, the morbid action of the bowels goes on, the frequency of the evacuations increasing, and the exhaustion of the patient hourly grows worse. If, as Dr. Atlee has said, the mere casting out of the contents of the bowels will prevent the liver-trouble, as in every case of cholera infantum the ingesta are fully removed in a few hours at most after the dawn of the attack,—indeed, in some cases where the result has been fatal, death has occurred in a few hours after the commencement of the attack,—in these the bowels have been entirely freed from ingesta, yet post-mortem examinations have revealed

congestion of the liver, and the gall-bladder empty or containing an abnormal bile. According to Dr. Atlee's views and statements, the emptying of the bowels should have prevented the hepatic trouble; yet the facts, not the fancies, are that the bowels were emptied, and promptly, too, but the emptying of them did not prevent hepatic trouble, as it should have done if the doctor's hypothesis is correct.

The doctrine of elimination of the contents of the bowels by evacuants, as being potent in the cure of bowel-affections, and especially of the use of castor-oil in repeated doses being a sovereign remedy for enteric diseases, and especially that Johnson, of London, has reported cases of cholera successfully treated by the use of castor-oil only, we are all, no doubt, quite familiar; but how many of us have confidence in Johnson's castor-oil treatment, and how many of us are ready to rely upon such treatment in cholera, is another matter. "I hesitate not," Dr. Nebinger said, "to speak for myself, and to say that I do not believe that a case of cholera was ever cured by the use of castor-oil or other evacuants, Johnson to the contrary notwithstanding."

In regard to all Dr. Atlee has said about the treatment of cholera infantum by locking up the irritating ingesta in the bowels by the use of astringents, cholera-mixtures, etc., Dr. Nebinger said that practically he did not know anything about such treatment, nor, with his views of the pathology of cholera infantum, could he ever know from practice anything about such treatment of the disease. The pathological views which he held in regard to cholera infantum, and which he had endeavored to present to the Society, suggested to him a rational treatment, which he pursued in the management of the disease, and with the results of which he was satisfied, and caused him, moreover, to regard as irrational such treatment as named by Dr. Atlee, and to conclude that when such treatment has been used with apparent success the *vis medicatrix nature* of the little patient has tided it safely over both the attack of the disease and the attack of the doctor.

Dr. Atlee says there are more potent causes than heat operating in large cities to originate and maintain cholera infantum. "Go," he remarks, "into our markets, and see the character of our milk and the other articles of food by which our children are fed. We find in them more efficient causes of intestinal disturbance than high thermometric condition of atmosphere." The doctor must not jump at conclusions: it is not safe to do so. It is true some babes are fed upon improper diet; but impure food will not account for the production of the disease in those—and such there are—who are not fed upon bad milk or an unwholesome diet of any kind: therefore, for these the doctor will have to find another cause for the production of cholera infantum in them than unwholesome diet. Dr. N. said he thought Dr. Atlee might find the cause to be the one he had suggested in his paper,—exalted atmospheric temperature, long continued. Dr. Atlee had asked him to explain how heat, or rather solar heat, produces congestion of the liver in cholera infantum. Dr. N. said he could not tell how solar heat congested the liver, but he presumed it did through the agency of the nerve-centres; but it does not follow because we cannot tell how a thing is done that it therefore is not done at all, as, for example, we know sunstroke is produced by solar heat; but because we cannot tell how it is produced, it does not follow that the sun or solar heat is not the agency by which sunstroke is produced.

Dr. N. said that he was in full sympathy with Dr. Atlee in the matter of the abuse which has been heaped upon the liver, and that he was aware that it had been charged with being the cause of bodily discomforts when it was innocent of all wrong; yet,

because it is occasionally charged with wrong-doing unjustly, we must not therefore conclude that it is never in fault. The spinal cord, the lungs, the heart, the spleen, the stomach, have all suffered from false accusations, and we must not neglect to say that the womb, above all other organs, has come in for an immensity of slander, and has not only been made the scapegoat of the wrong-doing of other organs, but it has, most unfortunately, been the shield of protection for ignorance and rapacity.

Dr. ESHLEMAN said he had no fixed idea of its pathology. He suspected that the primary lesion lay anterior to that of the alimentary canal and the abdominal viscera, *in the nerve-centres*. Remedies addressed to these, such as chloral, bromide of potassium, opium, and cool air, were no less essential in treatment than bismuth, aromatic syrup of galls, good milk, beef-juce, pepsin, brandy, and ice-water. So treated, he had not found the disease fatal.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

THURSDAY EVENING, JUNE 11, 1874.

THE PRESIDENT, DR. WM. PEPPER, in the chair.

DR. L. A. DUHRING presented a specimen of *angioma with sarcomatous degeneration*, and made the following remarks:

"The tumor which I present for examination possesses the following history: The patient was an Irishman, 50 years of age, with good general health, who stated that the growth began fifteen years ago. It first showed itself in the form of a small elevation or wart-like prominence. Its growth was very slow, especially for the first few years; of late it had evinced a disposition to more rapid development. At its commencement it was not painful, and caused him no inconvenience whatever; but since it had increased in size, within the last few years, it had been somewhat painful when squeezed or accidentally struck, and had been a source of 'worryment' to him.

"Upon inspection there was found a somewhat pendulous tumor, the size of a large hazel-nut, pedunculated, and seated upon the tissues of the left arm, at about the insertion of the deltoid muscle. It was soft and spongy to the touch, but could not be manipulated without causing decided pain. After prolonged gentle pressure it became quite distorted, but immediately regained its former shape and general appearance upon the removal of the force. It was a flaccid tumor, hung loosely from its pedicle over the skin of the arm, and could be moved readily from side to side in all directions. In form it was roundish and somewhat oblong, and possessed a smooth though corrugated surface. In color it was, when in its normal condition, dark-reddish, with a purplish hue in its most dependent parts; when exposed to manipulation or pressure the color varied, and showed many shades of red and purple. The growth manifestly contained blood in large quantities, which could be made to accumulate or disperse, according to the manner in which it was handled. There was no sign of ulceration or breaking down anywhere upon its surface, its structure throughout appearing to be uniformly distributed. The growth bore the general features of an erectile or vascular tumor. There was no pulsation perceptible.

"Immediately after removal, which was accomplished by an elliptical incision about the pedicle, including a considerable portion of skin and subcutaneous tissue, the tumor became softer, although it still retained its general form. But little blood escaped during the operation, and the patient made a favorable recovery.

The tumor was cut open directly after excision, and showed a grayish surface with numerous reddish puncta disseminated in an irregular manner. The tissue was soft and spongy, although quite firm, and exhibited no appearance of disintegration. It possessed a reticulated structure.

"Upon pressure, a very small amount of yellowish fluid mixed with blood oozed out, but there was no pure blood to be seen.

"A piece of tissue taken from the centre of the tumor

was hardened in a weak solution of chromic acid and alcohol, and in the form of thin sections submitted to the microscope. With a low power an irregularly-formed tissue is seen, characterized by bands of structure of various size, shape, and distribution, which are present in all parts of the field, constituting a large part of the growth. These bands are made up of connective-tissue elements, and comprise the reticular work already referred to as seen with the naked eye. It is at once observed that much of this mesh-work consists of blood-vessels which have been cut in the section, some evenly and others obliquely, giving rise to a number of appearances, and which go to render the tissue so ununiform. These blood-vessels are present in all sizes, some still containing coagula of blood, while others are empty, their walls alone being seen as rings of connective tissue; some have collapsed, while others have retained their naturally distended form, giving a net-like look to the structure. These openings are larger and more developed in some parts of the field than in others.

"In addition to this mesh-work of vessels, there is another element in the growth, of almost equal importance and interest. In these bands and rings and throughout the whole tissue there exists an active and abundant cell-formation, which may be seen permeating all parts of the tumor, and which has a large share in the growth as seen at the present time. These cells are for the most part round or roundish, contain a large nucleus, and vary greatly as to uniformity of size. They are crowded together in places, and are very numerous everywhere in the field. They are imbedded or seated upon a light, delicate connective tissue, from which they appear to spring. They may be seen invading the walls of the blood-vessels, where they produce an altered and abnormal appearance, destroying their sharpness of outline and changing their usual conformation. In certain fields the cells may be

noticed collected together or arranged in strings, like so many spores of a fungus. The interest which concerns this little tumor rests with the results of the microscopic examination. Clinically, it was judged to be a simple vascular tumor or angioma, of the cavernous variety; the view of its being of a sarcomatous nature never having been entertained, and yet the microscope reveals this element in a marked degree. Viewed simply as a microscopic specimen, apart from its gross physical or clinical appearances, it might with almost equal justice be ranged either among the sarcomata proper or with the angiomata.

"In certain examples of sarcoma the vascularity is quite extensively developed, the veins especially being enlarged; but in most cases this condition does not exist, the vascular structure being of secondary importance. In the tumor under consideration the veins, arteries, and capillaries appear, however, to be too largely and conspicuously developed to be viewed in the light of a secondary formation. The walls of the vessels, which we have seen to be infiltrated with cells, also show the vascular elements to be of earlier date than the cells, which seem to be just beginning to invade these structures. From these facts, there can be no question but that in the case before us we have an angioma of the cavernous type, in which has developed, as a secondary formation, round-celled sarcoma."

Dr. R. M. BERTOLET agreed with Dr. Duhring in his idea as to the relation of the two conditions, the vascularity and the subsequent sarcomatous degeneration. As to the other view, which would make it a sarcoma originally, in which we have this development of huge blood-vessels later, he did not think it so reasonable. It is true that some of the cases of *fungus hæmatodes* are examples of extremely vascular sarcoma, but such tumors are generally much more rapid in their growth, and present other characters different from those of the angioma. The nævi or mother's-marks upon the skin are very liable to be developed into some form of angioma, which may remain innocuous for a long period, but if there is a rapid and multiple development of pigmented growths upon the skin, the probabilities are that we have to deal with melanotic sarcomata.

Dr. C. H. BURNETT presented *polypi from the ear*, with portions of a *necrosed incus*, and read the following history: "These polypi were removed from the left ear of a boy 7 years old, at present in the surgical ward of the Presbyterian Hospital, where he has been operated upon for lesion of the knee-joint. The patient is of a remarkably scrofulous diathesis, having at present a scrofulous ulcer on the neck beneath the affected ear. I found a copious sanious and offensive discharge issuing from the left meatus when my attention was called to this case by the surgeon then in charge of the ward. The parents state that the discharge has existed for two years.

"There has been mastoid disease on each side, to the greatest extent, however, on the left side, where I found a wide depression, with a corrugated surface, as large as the end of one's thumb.

"On the right mastoid process, close to the auricle, directly behind the meatus, there is a small, round, and deep depression in the bone, marking, in all probability, the exit of a former sinus.

"Upon inspection of the left meatus, I found a polypus as large as a pea lying half-way down the passage, attached to the antero-superior wall by a short, thick pedicle. I removed the polypus by means of Blake's-Wilde's snare, and touched the cut surface of the pedicle with a drop or two of chloro-acetic acid. Its removal was attended by a slight hemorrhage. After the removal of this polypus and the cessation of the bleeding, I discovered a longer, deep-red body, lying on the floor of the meatus, which at first sight I considered

a clot of blood, and, seizing it with a pair of forceps, I gently removed it. As soon as it was removed from the auditory meatus, I discovered that it was an organized body, containing in its structure a large amount of fluid blood, and imbedded in it I found the accompanying piece of bone, which is a portion of one of the ossicles. Dr. H. Allen has examined this bone for me, and has pronounced it the long process of the incus. I could find no necrosed surface in the ear from which this piece of bone could have come, which fact would remove any doubts as to its true nature. The organized vesicle-like body of polypus containing fluid blood was placed in a solution of equal parts of water and glycerin, which soon became deeply stained with blood, leaving the membranous sac quite pale and flaccid.

"The first polypus, placed in the same preservative fluid, has retained its original shape and brownish color.

"The fetid discharge has ceased, in three weeks since the operation, under the use of daily syringing with Labarraque's solution and water (f3ss—Oj). The amount of hearing in this case could not be obtained, because the child belongs to that class, now and then seen in hospitals, which makes no reply to its superiors, but converses freely with its playmates, apparently hearing all that is said. There can be no doubt that the boy is deaf in the left ear, for inspection since the cessation of the discharge reveals the entire loss of the membrana tympani and all those portions of the ossicula auditus usually seen from the meatus. What the condition of the bodies of the ossicles may be, it is impossible to state. I believe the portion of the incus removed with the second polypoid growth became detached by a process of necrosis, but was mechanically retained in the meatus by the first polypus, which entirely occluded the meatus. The second growth, to which the long process of the incus adhered, was in all probability a polypus in the process of formation."

THE PRESIDENT mentioned a *morbid discharge* which he had met in the morning for the first time. It is the condition known by the French writers as *albuminoid expectoration*, which presents itself sometimes after paracæstesis of the chest. He had, in connection with Dr. Thos. J. Yarrow, drawn off from the chest of a patient with hydrothorax, probably connected with tuberculous disease of the pleura, seventy-five ounces of serum. The operation was easily performed with the aspirator, and gave the patient great relief; but towards the end of the operation there was grating of the roughened pleura against the canula, which caused him to desist. There also occurred, subsequently, some troublesome cough, which was, however, relieved by deodorized tincture of opium. The fluid drawn off promptly coagulated, the latter portion becoming semisolid, like soft jelly.

In about eighteen hours after the operation he began to expectorate very freely a peculiar matter, consisting of an abundant muco-fibrinous coagulum floating in a straw-colored serum, the amount raised in twenty-four hours being at least three gills. It resembled so closely the fluid drawn off from the chest as to attract the notice of the family. This peculiar expectoration corresponds with what has been described, especially by the French physicians. The amount which is reported to have been expectorated in some cases much exceeds what occurred here. Various explanations have been offered for this phenomenon, but no one seems to have entirely established itself. Some have attributed it to laceration of the lung and the escape of some of the pleural effusion through the bronchi, but such did not occur in this instance, since there was no hæmoptysis, pneumothorax, or other evidence of puncture of the lung-tissue.

It has also been suggested that this expectoration depends upon a rapid collateral œdema or transudation

into the bronchi, which occurs while the lung is expanding and returning to its original state; and this appears the most probable view of the matter.

The patient had a dangerous syncopal attack six or seven hours after the operation, from which he was, however, aroused by stimulants.

Dr. J. EWING MEARS asked the President whether the formation of the coagulum in the fluid drawn off would not imply to a certain extent the existence of inflammation. He had observed that wherever this had occurred in fluids derived from tapping the abdomen, there had been inflammatory action. He had never observed it in pure *hydro-peritoneum*, in which the fluid is a true transudation and resembles more or less closely the serum of the blood.

THE PRESIDENT replied that while he thought that the presence of a large amount of this coagulum favored the view of inflammatory action of a certain grade, he had also observed it to take place more or less in all effusions. In effusions attending cirrhosis of the liver, where, although the peritoneum was altered, there had been no inflammation, he had frequently seen after ten or twelve hours flocculi of this substance. He had seen it also in the fluid of non-inflammatory hydrocele and in pleural effusions attending heart-disease. Where, however, as already stated, the amount of this coagulum is large, he considered it to a certain extent evidence of inflammatory action.

Dr. MEARS said he had asked the question more particularly in relation to the character as possessed by the expectoration.

Dr. BERTOLET said that it was readily conceivable that we might have this expectoration without any previous inflammation, if we considered the analogous process where, in consequence of occlusion of a smaller bronchus, either by the entrance of a foreign body or by plugging with inspissated secretions, there is brought about a collapse of the lung-tissue supplied by the obstructed bronchiole. The wedge-shaped portions of the lung in which there has been thus acquired atelectasis soon become hyperæmic, followed by an exudation of serum and blood. This subsequent œdema or splenization does not imply an inflammatory condition, but results from mechanical causes, such as stasis and the removal of the internal pressure of the atmosphere. In the operation for paracentesis, the external pressure is removed from the more or less completely collapsed lung, and again the conditions are favorable for the transudation of the liquid and solid constituents of the blood into the air-vesicles; but here, since there is no obstruction of the bronchioles, it is readily expectorated.

Dr. B. suggested the use of Donnie's liq. potassa test for pus, in another instance, with a view of determining more precisely the condition of the expectorated matter.

voted to the field of toxicology—needs all the light that the most powerful lenses of thought and intellect can concentrate upon it. Human life may hang upon the faintest diversity of hue in a chemical reaction, and justice be made more hopelessly blind by the dust thrown into her eyes by the pretentious and ignorant of both professions. It is fearful to think of the risks of life to which the innocent have been subjected, and of the insufficiency of scientific testimony which has afforded loopholes for the escape of the guilty, as we reflect upon the great criminal trials of the past. Doubtless, a single fallacious test, a color that told a false and fleeting story, a symptom whose very intensity was an unreliable diagnostic sign, were sufficient, in numerous instances, to acquit the guilty or condemn the innocent. In these days, however, each new case of medico-legal interest seems to develop the necessity of thoroughness in the appreciation of every detail of test and symptom, and of a completely exhaustive analysis, which should be followed by testimony in the witness-box the accuracy of which should be unquestioned and unquestionable. As Prof. Reese justly remarks, the great leading idea that ought to govern the toxicologist in all his chemical investigations is, not to see with how small a number of tests he can prove the presence of the poison sought for, but rather how many different tests he can adduce to prove his point. The author states, however, that a veteran chemist has rather boastfully asserted on the witness stand that, in making an analysis for poison in a capital case, if he had satisfied himself of its presence by one or two tests, any further experiments were quite unnecessary.

A poison is well defined by Prof. Reese as "a substance capable of producing noxious and even fatal effects upon the system, no matter by what avenue it be introduced; and this, as an ordinary result, in a healthy state of the body, and not by a mechanical action." The question of *quantity* is sensibly left out, for "the mere quantity of the substance required to destroy life cannot be made a ground of distinction between a poisonous and a (so-called) non-poisonous article."

The number of poisonous substances detected in the blood, the secretions, and the tissues and organs of the body, has wonderfully increased since the days of Orfila, whose published account limited them to comparative numerical insignificance when contrasted with those detected by more recent investigators. The effects of various physiological conditions are ably discussed in a chapter on the "Mode of Action of Poisons on the Animal Economy," the author stating that "there is good reason to believe that the poison is active only while circulating in the capillary blood-vessels. It is a very common mistake to suppose that death is caused by the very poison discovered in the stomach; the death being, in point of fact, attributable to the absorbed portion only (except in the case of the corrosives). The quantity remaining in the stomach after death is the surplus of what was necessary to kill."

A chapter of especial interest to the defendant in a medico-legal case and his counsel includes an inquiry into the possibility of imbibition of poisons after death. "Is it possible," says the author, "for a dead body to imbibe a poisonous substance from the soil in which it has been interred? Is it possible that a poison introduced into the stomach or the rectum, or by the hypodermic method, after death, should pass through the tissues by imbibition into other viscera of the body, so as to give rise to the suspicion of poisoning, when, in reality, the death had resulted from a different cause?" In regard to the first branch of the proposition,—cemetery-poisoning,—arsenic being the only substance in dispute,—Prof. Reese considers that it is impossible, from the insolubility of that substance and the absence of direct chemical action, that it should be capable of

REVIEWS AND BOOK NOTICES.

A MANUAL OF TOXICOLOGY, including the Consideration of the Nature, Properties, Effects, and Means of Detection of Poisons; more especially in their Medico-Legal Relations. By JOHN J. REESE, M.D., Professor of Medical Jurisprudence and Toxicology in the University of Pennsylvania, etc. 8vo, pp. 507. Philadelphia, J. B. Lippincott & Co., 1874.

As the result of the labors of a skilful, earnest, and enthusiastic practitioner and teacher, who has devoted some of his best efforts to the unravelling of medico-legal intricacies, this new and original work creates for itself an elevated position among the standard books of its special department. The particular branch of medical jurisprudence which it investigates—that de-

such transudation. "If the poison was deposited in the organs during life by absorption, the viscera will contain as much of the poison in their interior as on their surface, which would not be the case if they had derived it by post-mortem imbibition. But if the poison is found in the organs of a body after many years' interment, then the objection may be very plausibly urged that its presence in the different viscera may be ascribed to imbibition from the stomach and bowels."

The practitioner must endeavor to cultivate an accurate knowledge of the evidences of poisoning as derived from symptoms, post-mortem examination, chemical analysis, etc. It would be improper, as a general rule, to convict on any one link in the chain, unless some other corroborative link were added. Certainly, so far as symptoms are concerned, the view of Orfila that a case of poisoning can never be proved by them alone is the correct one, inasmuch as there are no characteristic symptoms of any single poison. If it were possible to decide on symptoms alone, as the author remarks, there would be no necessity for a chemical analysis. Although it is possible to establish the fact of poisoning without any chemical analysis, the public at large is not satisfied that justice has been done to or for the prisoner until the refinements of chemical manipulation have been brought to bear upon all matters at issue admitting of such an application. The author contends that the experimenter should never be satisfied with the results obtained from a single test or from a single line of testing. "Thus, in testing for prussic acid, the analyst is not justified in stating, as was done in the Schoeppe case, that this poison was present, simply because 'faint traces' were observed by the application of only two out of the four recognized tests for this substance, and one of these (the iron test) very doubtful."

He states that, in all cases of poisoning by the metallic compounds (arsenic, antimony, mercury, etc.), it is essential to obtain the *metal*, and in such quantity as to enable it to be subjected to all the corroborative tests.

Important as color-tests are, they are frequently fallacious, and the author gives several excellent reasons for the avoidance of a merely mechanical reliance on color alone. Honorable participation in recent medico-legal cases has given Prof. Reese much food for reflection on this point.

"Even the well-known and characteristic color-test of strychnia, which is not imitated by any other known substance, should not be exclusively relied upon in a criminal case, but ought to be corroborated by other tests."

A chapter is devoted to "Compound Poisoning" and the "Antagonism of Poisons," the former having excited popular interest recently from the effort to prove in the Schoeppe case that prussic acid and morphia had both been administered. In regard to the antagonistic action of poisons, as prussic acid and morphia, it is difficult to draw any absolutely conclusive inferences from experiments on the lower animals, in which the toleration for certain agents is sometimes even greater than in man.

Of late years the public has been naturally perplexed in the employment of the expressions *expert* and *expert testimony*. Unfortunately, as usually presented in criminal cases, medico-legal questions become so frequently the texts for quibbling and contention, that in the confusion of discordant testimony they elicit but little sympathy for either of the learned professions interested. An expert should be uniformly "a skilled witness; one who has accurate knowledge of the matter under consideration;" but it must be rather mortifying to one really deserving of such an appellation to find the term bestowed on all those whom the lawyers on either side may so designate, and semi-scientific tes-

timony quoted and discussed as if it had the weight of authority. The whole system does injustice to superior intelligence and culture, when brought in public collision with mediocrity in the court-room.

"If it were only possible," as the author remarks, "to exclude these improvised experts from poison-trials, and confide the responsibility to men of known and recognized toxicological ability, there would occur far fewer occasions in which this conflict of expert-testimony would be witnessed; for it is to be observed that among *genuine* experts—persons of purely scientific attainments, uninfluenced by either prejudice or favor, not mere partisans—this difference of opinion on a purely professional subject is much less likely to occur. In Germany, the experts first summoned are exclusively those whom the State, after proper examination of their competency and skill in such particular inquiries, has duly authorized to act for this purpose; while in addition to this, there is organized a tribunal of experts, to which the opinions of expert witnesses can be referred." We heartily agree with the author that adequate compensation should be given to expert witnesses, commensurate with the high duties they have to perform and the great importance of their testimony.

The greater portion of the work is devoted to poisons proper, their actions, antidotes, tests, etc., embracing all the light which modern investigation has thrown upon the methods of analysis and detection. The classification adopted is modified from that of Taylor.

We cannot do otherwise than commend the writer of this excellent volume for the good taste he has displayed in avoiding personal allusions, such as might very readily have been anticipated from one whose recent testimony in several important criminal cases had brought him into controversy with men of opposite and inflexible views. By thus keeping his work within strictly scientific limits, much more importance is given to the results of his labors. The book, resting on its own merits, on the reputation of its author, and on the importance of its subject, will, we trust, take a well-deserved place as a standard authority on toxicology. In conclusion, we may add that the volume is issued in a handsome and attractive style of typographical execution.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM JULY 28 TO AUGUST 3, 1874, INCLUSIVE.

- BROWN, JOS. R., SURGEON.—Relieved from duty as Medical Director of this Department, having been appointed President of the Army Medical Examining Board, to meet in New York City on August 4, 1874. G. O. 7, Department of the Platte, July 23, 1874.
- PAGE, CHARLES, SURGEON.—To act as Medical Director of this Department until the arrival of the medical officer ordered to that duty. G. O. 7, c. s., Department of the Platte.
- RANDOLPH, JOHN F., SURGEON.—Granted leave of absence for thirty days. S. O. 104, Department of the Platte, July 29, 1874.
- WRIGHT, J. P., SURGEON.—Assigned to duty at Fort Hays, Kansas. S. O. 117, Department of the Missouri, July 30, 1874.
- GRAY, C. C., SURGEON.—When relieved by Assistant-Surgeon Middleton, to proceed to Fort Duncan, Texas, for duty at that Post. S. O. 116, Department of Texas, July 28, 1874.
- JANEWAY, J. H., ASSISTANT-SURGEON.—When relieved by Surgeon Wright, to proceed to Fort Wallace, Kansas, for duty at that Post. S. O. 117, c. s., Department of the Missouri.
- WATERS, W. E., ASSISTANT-SURGEON.—To proceed, without delay, to Fort Dodge, Kansas, and report in person to Colonel N. A. Miles, 5th Infantry, for duty. S. O. 116, Department of the Missouri, July 29, 1874.
- MIDDLETON, P., ASSISTANT-SURGEON.—Assigned to duty at Fort Clark, Texas. S. O. 116, c. s., Department of Texas.
- KING, J. H. T., ASSISTANT-SURGEON.—Granted leave of absence for ten days. S. O. 149, Military Division of the Atlantic, August 1, 1874.

SATURDAY, AUGUST 15, 1874.

ORIGINAL COMMUNICATIONS.

PAROTITIS, TRANSLATION TO TESTIS AND BRAIN, WITH THREATENED ACUTE MANIA—RECOVERY.

BY S. J. RADCLIFFE, M.D.,

Washington, D.C.

G. W. D., 17 years old, of good physique, fair complexion, auburn hair, and heretofore in good health, with no known hereditary tendency to disease, called at my office August 16 last, complaining of sore throat. I examined his throat, and found the tonsils and pillars of the fauces slightly inflamed and swollen, but no fever or other constitutional disturbance. The next morning I found his tonsils and fauces still inflamed and swollen, some difficulty and pain in swallowing, jaws a little stiff and slightly swollen about the angles and below the ears, pulse accelerated, bowels slightly constipated, face flushed, and altogether feeling rather badly. He was ordered a diaphoretic, and warm flannel applied to the face and neck.

18th.—Very little change, except more swelling and pain at the seat of the parotid gland, and general malaise. Treatment continued the same.

19th.—Symptoms somewhat increased in intensity; more fever, temperature higher, pulse fuller and stronger—96 beats to the minute, jaws more stiff, throat quite sore, considerable difficulty in opening the mouth, tongue coated white, right testicle slightly swollen and painful on motion or to the touch, and less swelling on the right side of the face than on the left; bowels sufficiently open.

20th.—Fever increased, pulse 110, temperature 101.5°, face much swollen, swelling and pain of right testicle greatly increased; very restless; but little sleep during the night, with some delirium. Continued the diaphoretic, with warm flannel to the testicle and camphorated liniment to the right side of the face.

21st.—Fever high, pulse 120, and bounding; skin hot and dry, temperature 102.6°, tongue heavily furred, mouth dry and clammy, bowels constipated; no sleep, and quite delirious most of the night; constant nausea, with efforts at vomiting; testicle enormously enlarged, and extremely painful on the slightest motion. No priapism observed. Solution of citrate of magnesium was ordered, and to be repeated until free catharsis was produced. Diaphoretic continued; flaxseed-meal poultices to envelop the entire throat and sides of the jaws from ear to ear; warm flannel applied to the testicle, which was suspended by a roller of flannel; and lumps of ice to quench thirst allowed as desired.

22d, 11 A.M.—Perspired profusely during the night; clothes drenched; fever gone; temperature 99°, pulse 85, and soft; skin moist; bowels moved two or three times freely; quite comfortable; jaws and testicle still much swollen, but not so painful; tongue looks better; can swallow better.

5 P.M.—Expressed himself as feeling quite comfortable, and was doing well. There was every indication now that the disease had spent its force, that it would terminate favorably as usual, and that nothing more was to be feared.

23d, 11 A.M.—Still doing well, and convalescence seemed about to be established, except that he was rather restless and did not sleep soundly or continuously during the night, but was wakeful and fretful, complaining of little things that annoyed him; would ring for the servants at unusual times, and be very im-

patient until they obeyed his summons. His tongue continued pasty; still some desire for ice. Swelling of the face and testis decreased.

5 P.M.—No material change.

24th, 11 A.M.—Some symptoms of cerebral excitement developed during the past twelve hours. Sleeplessness; continued restlessness; exceedingly irritable on the slightest provocation; rapid and continued talking, which was very exhausting to him, and mostly upon one subject. He considered himself well, and strenuously resisted restraint. He had no desire for food; gulped down everything given him simply to get rid of it, or to please those giving it. Could not be induced to remain in bed; constant desire to get up and dress. Pulse 110, sharp and unsteady; eyes bright and staring, pupils contracted, tongue pasty, mouth clammy, surface cool, looked worn. Swelling of face and testicle subsiding. These symptoms continued for some days, without much change. We tried to treat the matter as if his peculiarities were simply the result of the usual and natural peevishness due to sickness and the debility following. We therefore disregarded them to a great extent, and only watched him, taking care not to cross him, but to satisfy his whims as far as possible, and wait results. I directed fifteen grains of bromide of potassium to be given him every two hours, with a drachm of elixir of valerianate of ammonium added, and enjoined decided rest and quiet.

27th, 11 A.M.—On calling as usual, his mother informed me in great alarm that George, in his weak and feeble condition, had slightly dressed, and left the house without the knowledge of any one; had gained access to the stable in a clandestine manner by climbing in the window, the door being locked; had saddled and bridled the most fractious of the horses, and ridden off they knew not whither. His father found him, after a wide search, in an exhausted condition on the street, about 2½ P.M., and sent him home in a street-car under the protection of a friend. At 5 P.M. I found him wild with excitement, with great cerebral disturbance, talking rapidly and warmly, but with some coherency, principally upon one subject, repeating it over and over again, as if his previous remarks had not been impressed upon his hearers, and occasionally with a smile and with seeming enjoyment; dwelling, also, largely upon his exploits during the day, with a desire to justify or to explain the cause of them. His pulse was 120, weak and tremulous; skin cool, head hot; a flush like that of hectic on his cheeks; cheeks hollow, eyes staring, pupils contracted, mouth clammy, requiring frequent sips of water to enable him to talk; restless, not easily restrained; not easily turned from his train of thought; swelling of the jaws nearly disappeared; swelling of the testis nearly gone. The bromide of potassium was increased to thirty grains every two hours, without the elixir of valerianate of ammonium, until sleep or quiet was produced; to be kept perfectly quiet, and his talk not encouraged.

28th, 11 A.M.—Met Dr. Basil Norris, U.S.A., in consultation, but we learned at our visit that after a rather restless night our patient had fallen asleep at 6½ A.M., and was still asleep, and we deemed it advisable not to awake him. At 3 o'clock P.M. he was still asleep and quiet.

29th, 11 A.M.—We were informed that our patient had slept until 6 P.M. the evening before, and most of the past night. We found him sitting with a young friend at a writing-table, laboring under great mental excitement about some letters he desired to write to friends, so he might get his mind clear of all such things, or "get them off his mind," as he would say. His friend sat perfectly resigned and under his control, and wrote whatever he dictated. He had a number before him ready

for the mail, and was still dictating more. His principal theme was his studies and his return to school at Exeter immediately, and he was constantly making his plans for the purpose. Another subject that seemed to irritate him was that he thought his father, who had obtained an appointment for him, desired him to go to the United States Naval Academy at Annapolis; he did not wish to go, and when his father dissipated that idea from his mind he seemed very much elated. He complained a good deal of headache, of weariness, of being easily fatigued, and seemed to appreciate the fact that his mental faculties were not under control. His pulse continued rapid, the surface cool, the head hot, and the mouth and tongue pasty. We directed the bromide to be continued, and our patient to be kept in his room and watched.

30th.—Slept most of the past night; somewhat refreshed, but still talks; still writing letters with the aid of his friend; still restless and irritable. He had no desire for food, but drank or sipped ice-water frequently. He would take a little fruit now and then, which he seemed to enjoy. He promised me he would write no more letters for a week, and put up his materials.

31st.—Little quieter; slept but little past night; still considerable disturbance of the functions of the brain; general condition about the same. He desires to go out, and can scarcely be restrained from doing so.

2½ P.M.—Had a consultation with Dr. C. H. Nichols, of the Asylum St. Elizabeth, D.C., in regard to the patient. We found him without amendment, and the diagnosis was fully confirmed that he was laboring under a high state of meningeal excitement or hyperæmia, influencing the brain to increased functional activity, due to translation or operation of the materies morbi of the mumps; and he was considered threatened and to be in great danger of acute mania. The bromide of potassium was directed to be continued, with hot sitz-baths, made stimulating by mustard, and cooling and evaporating applications to the head frequently through the day; not to be allowed to go out; not to be exposed to any bright light, but kept generally in a moderately dark room.

Sept. 3.—He continued with very little change to this date. His pulse varied from 100 to 110; temperature about normal, though to the touch the surface was cool, while he complained of cold feet and hot head. A hot brick had to be put to his feet frequently at night. His tongue continued pasty, with some thirst, and anorexia was almost complete.

4th.—Pulse 90, tongue disposed to clean, mouth moister, not so thirsty, the general circulation better, not quite so irritable, sleeps a little better. Treatment continued, though less frequently.

5th.—Still improving; pulse 78, tongue cleaning, eats better.

8th.—Out walking during the morning. Went to church yesterday. Seemed much better; was quiet and composed, and much less inclined to talk.

18th.—A decided change had taken place for the better. Had much improved in general health. The functions of the different organs were more regular, and normal; though he was still somewhat impatient and irritable.

20th.—His father called to see me, and said George had some return of excitement the day before. He had taken a ride on horseback with a lady, which had upset him. He said he was very restless during the night; imagined he saw objects entering the room; was quite timid, requiring him to remain with him all night; and he feared a return of the trouble. I directed him to give him the bromide again, which had been suspended for a day or two, and to keep him from any sources of excitement.

Oct. 1.—Had made frequent inquiries about the patient, and learned that he was daily improving in general health, daily becoming "more like himself," and had greatly improved in mental acumen, without any return of the aberration from which he had suffered.

22d.—Called, but found the patient out. His mother informed me his father desired, as he had so much improved, he should be engaged in some light occupation to amuse him as well as instruct him, and, though he did not wish him to take up a regular course of studies thought the study of anatomy would be a pleasing pastime for him during the winter, which would afterwards probably lead to something more extensive. Consequently, on the 24th of October he matriculated at one of our medical colleges, and attended the course on anatomy.

June 20, 1874.—Received an appointment in the U.S. Coast Survey, and is now, July 16, on the Lakes in that capacity. His health, mental and physical, seems entirely re-established.

I have been induced to record this case of parotitis, because of the rarity of the sequelæ. I have been able to find but few cases of parotitis with brain-complications even hinted at, and the literature of the subject is so decidedly meagre that most of the authors who speak of it at all do so only as a probable result. Whatever may be the cause of the limited extent of the writings on this branch of the practice, whether from want of observation or otherwise, it is nevertheless true that, whenever this lesion is even mentioned, it is said to be of very unusual or rare occurrence; and its pathology is even now really a matter of conjecture or doubt.

Chelius, "System of Surgery," by South, vol. i. 1847, p. 167, gives the following as the literature of inflammation of the parotid, viz.:

Laghi, T., *Historia Epidemicæ Constitutionis, in quâ Parotides seroso glutine tumentes redduntur quæ Anno 1753 Bononiæ contigit in Comment.* Bonn, vol. v. p. 1.

Hamilton, R., *Account of Distemper by the Common People in England vulgarly called the Mumps, in Trans. of Royal Soc. of Edinburgh*, vol. ii. p. 59, 1790.

Hoff, *Diss. de Anginæ Parotidiæ.* Goetting., 1799.

Breurecke, *Diss. Anginæ Parotidiæ Descriptio pathologico-therapeutico.* Helmst., 1804.

Burns, Allen, *Observations on the Surgical Anatomy of the Head and Neck.* Edinburgh, 1811, octavo.

Good, Mason, M.D., *Study of Medicine.* Lond., 2d edition, 1825, vol. vii.

Since that period nothing has been written worthy to be distinguished as a monograph, though a very few isolated cases may be found in the journals, having reference more to the orchitis and other complications, as ovarian, uterine, or leucorrhœal, than to the brain. I have run over the journals for the past half-century, and am surprised to find so little bearing on this particular point. Our standard works and text-books are our only guides in the matter.

In the Catalogue of the Library of the Surgeon-General's Office, U.S.A., with an Alphabetical Index of Subjects, edition of 1872, there is nothing on parotitis as a distinct subject. In the edition for

1873 there is, I believe, but one in the English language, and but a few in the French language, and these are only theses for the doctorate. The following are those relating to metastasis, principally to the testes, and those of a sympathetic nature, and mostly connected with a typhoid state, viz.:

Rodburg, 1727; J. Joseph, 1792; Callenfels, 1815; Lortet, 1819; Delissalde, 1822; Rahwande, 1831; Brillat-Savarin, 1854; and Debize, 1869. The latter I have looked over,—viz.: Thèse pour le Doctorat en Médecine, de l'Etat Typhoid dans les Oreillons. Par François Debize, Paris, 1869,—and find that it makes no mention *per se* of metastasis to the brain. His principal proposition may be summed up in the following: "Nous considérerons les oreillons comme une maladie générale qui frappe le testicule au même titre que la parotide; la localisation de la maladie se fait, il est vrai, le plus souvent sur la région parotidienne, mais les autres déterminations morbides se faisaient sous l'influence de la cause générale sur des tissus ayant une composition et des fonctions analogues." This thesis refers to the other writers, but nothing further is elicited bearing on the point at issue.

Dr. Harvey Lindsley, of this city, reports, in the *Stethoscope and Virginia Medical Gazette*, vol. i., 1851, pp. 15 and 16, two cases of mumps with metastasis to the brain, both terminating fatally. He says, "Cases of mumps with determination to the brain are so exceedingly rare that I do not recollect to have seen or read of more than three besides those referred to at the head of this article. Most of our popular writers on the practice of medicine, though men of extensive experience, have evidently never seen a case, while they still speak of it as of occasional occurrence. This is the fact with Good, Eberly, Dewees, McIntire, Wood, Watson, Tweedie, etc., and indeed the only author who speaks of this complaint as having come under his own observation is Dr. Dickson, of Charleston, in his able and interesting work published a few years since." These were doubtless cases of real cerebritis, as post-mortem examination of the second case revealed extensive cerebral congestion. They died within four days of attack.

From the leading works on the practice of medicine, I find only the following, briefly summarized:

Austin Flint (Practice of Medicine, 2d ed., 1867, p. 370) says, "The parotid gland appears to be the seat of the disease, but it evidently involves a constitutional morbid condition, and a special causation. . . . Occasionally during the progress of the disease, or when the affection of the parotid is about to disappear, swelling, pain, and soreness of one or both of the testes occur. This must be extremely rare. I have met with but a single example. In the female, it is stated, the mammary gland and the labia majora are liable to become affected. I have never met with an example. When parts other than the parotid are involved, it is not from a metastasis, but from the operation of the same internal morbid condition which occasions the parotitis. . . . The disease, except that it occasions discomfort, is always trivial. The popular apprehension of danger from 'taking cold'

in this disease is based on the idea that if the affection of the parotid be arrested a metastasis is apt to take place. There is little ground for this idea. . . . The prognosis is always favorable."

In Reynolds's System of Medicine, vol. i., Lond., 1866, p. 229, Dr. Sydney Ringer, article "Parotitis," defines it to be "an acute febrile disease characterized by an anatomical lesion situated in one or both parotid glands, which runs a short course, and almost invariably terminates favorably. . . . Other organs besides the parotid and submaxillary may be affected. . . . The testicles, one or both, may suffer, while in the female the mammæ, the labia majora, and uterus are the parts occasionally attacked. These complications, or metastases as they are called, usually make their appearance whilst the parotid and the submaxillary glands are enlarged; but, on the other hand, the swelling may subside and disappear from the glands, and not make its appearance elsewhere until a period varying from a few hours to one or two days has elapsed. . . . In mumps, have we primarily a general disease of which the local effects are the sequence, or, on the other hand, is the disease in the first instance local, and are the general symptoms dependent on such local mischief? In the present state of medical knowledge *this question cannot be answered.*"

Niemeyer (vol. i. p. 436, *et seq.*) divides parotitis into two varieties: 1, idiopathic parotitis (mumps); 2, symptomatic or metastatic parotitis. He says, "Trustworthy observations render it most probable that the disease (idiopathic parotitis) spreads by contagion. It does not appear to us justifiable (with Rilliet) to consider mumps as an infectious disease, and the inflammation of the parotid gland the local expression of a constitutional disease, and to regard it as analogous to the affections of the skin that accompany the acute infectious diseases. We do not exactly know the ultimate anatomical changes of parotitis. . . . Nevertheless, . . . we may believe that it is chiefly or solely caused by serous exudation. Occasionally in the course of the disease one of the testicles is affected by an inflammation similar to that of the parotid. . . . And cases have also been recorded where, in the course of *idiopathic* parotitis, fatal meningitis has been developed. Infiltration with fibrous exudation and suppuration rarely occur in parotitis."

William Aitkin, M.D., Edinburgh (Science and Practice of Medicine, edited by Meredith Clymer, Philadelphia, 1866, vol. ii.), defines "mumps, parotitis," to be "an inflammation of the parotid gland, probably specific, and certainly in some cases contagious. . . . It is rare that the inflammation ends in suppuration. Occasionally during the course of the disease, but generally during its subsidence, the testicles swell, or the mammæ in the female; and in some cases the cerebral membranes become implicated, as also the gastro-enteric mucous membrane."

Chelius (A System of Surgery, by South, 1847, vol. i. p. 168) says, "As the swelling of the parotid gland subsides, a fresh attack of fever, with severe shivering, with pain in the loins and pubes, takes place, followed by inflammatory swelling of the tes-

ticles, and, in women, of the breasts and pubis. Other parts are also frequently attacked. Drowsiness, severe headache, wanderings, inflammatory or spasmodic affections of the breasts, active vomiting, dropsical swelling of the whole body, with short breathing and high fever, occur. The passage of this inflammation into suppuration . . . is very rare."

Watson (Lectures on the Principles and Practice of Physic, pp. 433-4) says, "Another curious circumstance connected with the disease, and one which has some bearing on its treatment, is that in many cases on the subsidence of the swelling of the neck and throat, and particularly when it subsides quickly, the testicles in the male sex become swollen and tender, and the mammæ in the female. But sometimes a more serious transference takes place,—from the testicle to the brain. This I have never witnessed; but then, to say the truth, I have not often been called upon to treat the mumps, and my personal experience of it is limited. Fortunately, the metastasis to the brain is much more rare than to the testicles."

Churchill (Diseases of Infants and Children) quotes Dr. Dewees, p. 415, as saying, "In the male we *once* saw the testes prodigiously enlarged. Much suffering was endured, and great hazard was incurred by the change. Violent fever and delirium accompanied this change of seat of the disease, and it required very active remedies to subdue them."

Churchill also says, "Again, a similar metastasis *may* take place, and the brain or its membranes become the seat of the secondary attack; and this is more frequent, Dr. Stewart thinks, in cases where no metastasis to the testes or mammæ takes place. This cerebral metastasis is highly dangerous."

Charles West (Diseases of Infancy and Childhood, 4th American edition, Philadelphia, 1866), says, "The occurrence of suppuration in the neighborhood of the gland is a rare termination of the inflammation, but is, I believe, oftener met with in children than in those who are approaching the period of puberty. On the other hand, metastasis of the disease from the parotid to the mamma, the testicle, or the brain, of all of which instances are on record by different writers, appears to be rare in proportion to the tender age of the patient. The most formidable of these metastases, indeed,—that to the brain,—would seem to be an accident very seldom met with; and neither of it nor of the translation of the disease to the mamma or the testicle can I say anything *from personal experience*."

Edward Ellis, M.D. (A Practical Manual of the Diseases of Children, with a Formulary, London, 1869, p. 184), says, "or, metastasis *may* occur, a remarkable feature of this disease to be remembered and watched for; and such metastasis may be either to the brain, which is highly dangerous, and exhibits itself either in coma or delirium, and may end fatally in a few hours, or to the mammæ of the girls and the testes of the boys."

Tanner (Practice of Medicine, American, from 5th London edition, 1866, p. 407): "Cyanche parotideæ, or parotitis, or mumps, is a specific contagious inflammatory disease of the salivary glands,

and of the parotid gland especially. . . . When orchitis has occurred during the prevalence of mumps, it has usually been considered as the result of metastasis."

From the varied views, therefore, expressed by the authors quoted above, an opinion can scarcely be ventured; nor does clinical experience or therapeutics teach us the real nature of that anomalous affection called mumps. Clinical observation alone teaches us that ordinarily in mumps we have to deal with a very simple, tractable disease, and therapeutics develops the fact that remedies are not *always* necessary to guide it to a favorable termination. Yet now and then it becomes formidable, putting at defiance our knowledge, experience, and treatment, and seems to run rampant without let or hindrance, and to increase the violence and danger of other diseases, as epidemics of typhoid and catarrhal affections, in which it frequently mingles its specific character.

Thus it will be seen that—1. Most authors speak of parotitis as trivial. 2. Some regard it as a local, while others regard it as a constitutional disease, while still others state that in the present state of medical knowledge the question cannot be answered, though Virchow, and also Niemeyer, maintain that the affection starts in the gland-ducts of the parotid; and, more recently, Dr. Bouchut, in a note communicated to the Academy of Sciences by Claude Bernard, states that "parotitis is simply a salivary retention, due to catarrhal inflammation" (*New York Medical Record*, September 16, 1873, p. 454). 3. Therefore, while some discard the idea altogether of any metastatic influence, or even the word metastasis, as applied to it, others hold to the old opinion of metastasis. 4. Affections of the brain in the course of parotitis are mentioned by almost all writers as a probable result, and this seems to be simply an opinion passed from one to the other without proof or experience. All speak of it as of extremely rare occurrence. Some are candid enough to say they have never witnessed a case. 5. The few cases reported have all died within a few days. The cerebral symptoms increased, while the inflammation of the parotid decreased. In the case reported above, the cerebral symptoms seemed to begin when convalescence was about to commence,—after the commencement of the subsidence of the parotitis. 6. In regard to suppuration of the gland, one case came under my observation where both glands suppurred. See report of case in the *American Journal of the Medical Sciences*, vol. lii., 1867, p. 560.

CONTRIBUTIONS TO THE PATHOLOGY OF ADHERENT PLACENTA.

BY BEDFORD BROWN, M.D.,

Alexandria, Va.

WITH the hope of throwing some additional light on the nature of the causes and the pathology of adherent placenta, the history of six cases of this peculiar complication which came

under my own observation is given to the profession.

Two of these cases were in primiparæ. Three instances occurred in the same patient in three successive pregnancies. One was in a woman who had borne four children.

Case I.—M., a colored woman, aged about 22 years, being exposed much during the early months of her first pregnancy, contracted a subacute rheumatism, which continued to annoy her during the entire term. During the latter months of pregnancy pain and tenderness in a particular portion of the uterine region were present, which were attributed to rheumatic affection of the abdominal muscles.

After a tedious but otherwise natural labor, the placenta was found to be very firmly adherent to about one-half of its extent to the uterus. The adhesions were so strong that the adhering portion of the placenta had to be broken down and pinched off with the fingers, and removed in detached portions, the entire hand having been introduced into the cavity of the womb. The tissue of the placenta was not only indurated, but contained numerous points of calcareous deposit of various sizes. Alarming hemorrhage followed the operation. At the seat of placental attachment the uterine mucous membrane was evidently indurated, while a rugged exudative material was on its surface. In three or four days after delivery, a severe attack of acute articular rheumatism was developed in the joints of the lower extremities, which abated after several weeks' duration.

Case II.—Mrs. B., aged about 26 years, had pursued always a very active and industrious life, and had been subjected to much exposure, having been compelled to labor for her own support. Three or four years previous to marriage and pregnancy she had passed through a somewhat protracted attack of articular rheumatism, which had left some of the smaller joints enlarged. Her first labor, which was natural, was complicated by adherent placenta. A large portion of the after-birth, on introducing the hand, was found to be closely and firmly adherent, and had to be broken to pieces before detachment. This gave rise to copious hemorrhage. The structure of the placenta was filled with myriads of small calcareous deposits. Many of these little deposits adhered tenaciously to the thick exudation over the point of adhesion. After all of the adherent parts of the placenta had been removed, there still remained a rough membranous formation on that portion of the uterine surface, of almost cartilaginous hardness.

Case III.—This was a married woman, aged about 30, of the laboring class, and the mother of four children. Her labor was an easy one, but complicated with adherent placenta. An effort was made to remove the adhering portion, which was only partially successful, as the patient positively declined to submit to any further attempts. Consequently about one-fifth of the placenta was left in the uterus. For several days hemorrhage was troublesome. About the third day the lochial discharge became excessively fetid, which was soon followed by chill, fever, and great tympanites. The type of fever very soon, indeed almost from the beginning, assumed the adynamic form. For two weeks the discharge continued intolerably fetid, regardless of powerful deodorizers. Occasionally portions of decomposing placenta were discharged. Finally the discharges ceased to be offensive, and all the symptoms which but recently presented so grave a character speedily changed, and convalescence was soon established. This was manifestly a true case of septicæmic fever with inflammatory complication.

In many respects septicæmic fever resembles puerperal peritonitis, and is not always easily distinguished from it. The initiatory chill, fever, tympanites, and abdominal tenderness on pressure, are common to both. In simple septicæmia the symptoms of blood-poisoning from some septic cause, and presenting the gravest type of adynamia, are present from the beginning.

These symptoms always make their appearance simultaneously with an intolerably fetid character in the lochial discharge.

Nothing can be more intensely offensive than a putrescent decomposing placenta enclosed in a uterus, with a temperature varying from 98° to 106°. Thus the situation is peculiarly favorable in this living retort for the generation of offensive and poisonous gases.

These septic products are absorbed by the circulation as fast as generated, until the system is saturated. In these cases delirium, subsultus, dry and brown tongue, somnolence, vital prostration, are among the early symptoms; whereas in puerperal peritonitis the mind is generally clear, the tongue moist, and the strength not greatly impaired until the last, and, in truth, the peculiar features of adynamia are rarely present in the early stages of the attack. In one the vital fluid is first attacked with a dangerous poison, in the other the uterine and peritoneal structures with inflammation.

In regard to those peculiar cases, it is remarkable how small a portion of decaying placenta left in utero will become a source of septicæmia, and again how rapidly in a certain proportion of cases the septic symptoms will subside and the system recuperate after the cause is removed.

Cases have come under my own observation where small portions of placenta have been discharged in two or three days after labor, and after the placenta had escaped from the uterus by natural means, which doubtless had adhered to the uterus. In one case of natural labor, where the placenta had been expelled by natural means, and where to all appearances this body was perfect in form and appearance, in twenty-four hours a lobule was found protruding from the vagina, in every respect having the organized structure of the placenta, but distinct, and having a small pedicle which was the only means of connection with the placental mass, and which had probably adhered to the uterus. It appeared as a minute placenta.

Cases IV., V., and VI.—Mrs. R., a woman of 35 years, and the mother of three children, after a very protracted and severe attack of acute articular rheumatism which left one knee-joint completely ankylosed, and before complete recovery, became pregnant with her fourth child. During this entire pregnancy she continued to suffer from the rheumatic affection. In November, 1870, she was delivered of a living child, after a natural labor. The placenta was found to be very extensively and firmly adherent, probably to two-thirds of its surface. The medium of attachment was so tough and firm that it became necessary, in order to facilitate removal, to introduce the hand and break down the placenta, and remove it in detached portions. But the operation being a painful and tedious one, before completion the patient positively declined further inter-

ference, and consequently a portion of that body was left adhering to the uterus. During and after the operation, hemorrhage was very copious. The tissue of the placenta was softer than natural, and had apparently undergone a species of granular degeneration.

On the third day after delivery the lochial discharge became very offensive, and very soon chill and septicæmic fever of an adynamic type supervened.

The remains of the placenta occupied more than two weeks in dissolving and passing away. During this time the discharges were intolerably fetid. While this process was going on, the fever assumed the most serious and alarming type; but during the third week the lochiæ became natural, and the peculiar adynamic fever, which had reduced the patient to almost a hopeless condition, disappeared as if by magic.

In 1872 Mrs. R. again became pregnant, and was delivered of a living child. The placenta was found to be adherent in this instance also, but not to the extent as in the former case. All the adhering portion was carefully pinched off from the uterine surface. With the exception of some hemorrhage, no ill effects ensued.

It is proper to state here that the patient continued to suffer from rheumatic symptoms during this pregnancy.

In 1873 she again became pregnant. During this time she suffered considerably from her usual rheumatic affection.

In May, 1874, she was delivered of a large living child. On this, as on the two previous occasions, the placenta was adherent to fully one-half of its surface. The portion adhering was removed with the greatest care, by pinching every particle off. The medium of adhesion was composed of a very dense and tough exudation, apparently one-fourth of an inch thick. The hemorrhage was, for a time, quite copious.

While exploring the cavity during the operation, an indurated point was detected, very rugged and hard, and elevated above the mucous surface at least half an inch, and as large as the palm of the hand, surrounded with the soft and velvety mucous membrane of health, about the seat of the old placental adhesion. All of these adhesions were located in the front wall of the uterus.

In all of the cases of adhesive placenta which I have here reported, the females belonged either to the middle or lower classes, and were in the habit not only of performing daily labor, but also of frequent exposure to cold and wet.

During a practice extending over a period of more than twenty years, I have never witnessed an instance in the higher walks of life, or among the affluent. With but one exception, these females had been the subjects of a well-marked rheumatic diathesis.

Whether in these cases adherent placenta and rheumatic disease occupy the relationship of cause and effect, or, on the contrary, were merely coincidental, is a question of some interest. In five of the cases there were structural changes in the uterine tissue at the point of adhesion, indicating positively subacute inflammatory action of a circumscribed character; and though there was evidence also of degenerative change in the structure of the placenta, there was none of previous inflammation. But in the first case there were indications of organic uterine disease and placentitis, both associated in the same case. Two interesting questions naturally arise here: one, whether females who are the subjects of a rheumatic diathesis are more disposed to adherent placenta; the other,

whether or not the process of adhesion is the result of a local circumscribed inflammatory action of a rheumatic character, situated in the uterine tissue. The facts cited in the foregoing cases indicate very pointedly that the latter view is really the true one. There is another fact in connection with these cases, of interest: all of the children were not only living, but the most of them large and vigorous.

The history of these cases goes far to confirm the truth of the principle that evil consequences are infinitely more liable to result from leaving portions of placenta adhering to the walls of the uterus than from any mechanical injury inflicted during the operation of removing them from that organ; that while inflammation is rarely the consequence of the act of removal, septicæmia is the almost invariable result of leaving any portion in utero. It is astonishing how long a time a small portion of adherent placenta will require to undergo dissolution and discharge, and how little of it will act as a poisonous fountain to infect the system.

REPORT OF TWO CASES OF AMPUTATION IN WHICH A MODIFICATION OF THE ESMARCH APPARATUS WAS EMPLOYED.

BY J. EWING MEARS, M.D.,

Surgeon to the St. Mary's Hospital.

THE occurrence of paralysis of greater or less duration, consequent upon the employment of the Esmarch apparatus for bloodless operations, having been reported by Langenbeck, induced me, in the operations below reported, to substitute for the rubber tube as originally suggested by Esmarch a rubber band one-half the width of that which is applied to the extremity. This was done in the belief that the paralysis was caused by the direct and forcible pressure made by the tube over a limited surface, which it was hoped could be avoided by the use of the band, which would, as it were, distribute the pressure. It has been suggested, however, that it is not simply the pressure made by the tube which causes the impairment of nervous power in the part, but that accomplished by the entire bandage, applied as it is with firmness sufficient to expel the blood from the superficial and deep vessels of the part. Pressure so great as to accomplish this result must certainly affect both the large and the small nerve-trunks; at least, the benumbed feeling experienced after the application of the bandage would imply this.

In the cases thus far reported, the paralysis has disappeared under treatment which had to be continued for a variable length of time. It would therefore appear that whether the injurious effects were produced by the tube or by the tube and bandage combined, the pressure was not sufficient to destroy the integrity of the nerve-trunks and thus completely destroy their power of transmitting impressions. The experiments made by Dr. S. Weir Mitchell on the effects of pressure on nerves, and his remarks upon the subject in his admirable treatise on "Injuries of Nerves," are of interest in con-

nection with the conditions under discussion. In speaking of the mechanical influence of pressure, he says, "A nerve-trunk is made up of a multitude of tubes, the contents of which are so nearly fluid as probably to be capable of more or less movement to and fro. When to such a bundle we apply a tight ligature, no matter how soon it be relaxed, we annihilate at once all power of the nerve to transmit impressions past the injured zone. If, however, in place of this, we make *gradual and equal pressure*, we may so affect the nerve as for a time to destroy its power to carry impressions. Now, this is exactly what occurs in many cases of compression: the nerve is for a time incapacitated, but soon regains its normal abilities."

Even in the most exposed positions, as the median nerve in the middle third of the humerus, it is questionable whether the tube, applied with the firmness necessary to prevent the return of the blood to the vessels, could so far act as a ligature as permanently to injure the nerve. Without doubt it is capable of making such pressure as temporarily to destroy its power of carrying impressions. The band also applied to the entire extremity or the greater part of it makes forcible, but at the same time gradual and equal, pressure, and is quite sufficient, to my mind, to produce an interruption in the nervous current. It would seem, therefore, that paralysis both of sensation and of motion, to a greater or less extent, must necessarily follow upon the application of such pressure as will empty the deeper blood-vessels of a part and maintain them in this condition.

One of the cases in which the bandage was used being an amputation through the middle of the arm, it was of course impossible to gain any information upon this point from it. In the other the patient complained of numbness and loss of motion in the hand for ten days following the operation, although the bandage was applied only to the middle of the fore-arm.

Case I.—J. R., colored, æt. 37, has suffered from tertiary syphilis, losing cartilages and bones of the nose; at present is suffering from arthritis of the wrist-joint, which has undergone suppuration and has resisted all methods of treatment. The elbow-joint is also involved, being much enlarged, and showing evidences of suppuration within. The patient was placed upon tonic and specific treatment, which did not retard the progress of the disease and prevent deterioration of his health. The removal of the arm, so as to interrupt the constant drain upon his system, appeared to be the only plan of treatment which afforded any promise of success. In his wretched condition, destroyed as he almost seemed to be by the ravages of syphilis, it was a question whether interference with the knife would be followed by any reparative efforts on the part of nature. As will be seen, we were most happily disappointed in this respect. Covering the ulcerated surface with a compress (waxed paper is better), the wide band was applied, beginning at the fingers and continued to above the middle of the arm; the narrow band was then applied, and the wide one removed. Amputation by the anterior and posterior flap method was performed. The cut surfaces were perfectly bloodless-looking,—as expressed by one of the gentlemen present, like veal which had been well bled. Ligatures were applied to five arteries, which were pushed

out of the tissues, as it were, and were readily recognized. One small muscular branch was missed, and required ligature after the removal of the constricting band; slight oozing occurred, but was easily checked by the application of cold water; the flaps were sutured, and dry dressings were applied to the stump. Notwithstanding the most unfavorable surroundings, the patient recovered without an untoward symptom. The operation did not appear to produce any shock, the pulse maintaining a uniform rate and volume from the first. There were present at the operation Drs. Owen, U.S.N., Austin, Mann, Barr, Purcell, and Mr. Soder, medical student. To Dr. Purcell and Mr. Soder much credit is due for their faithful care of the patient.

In reviewing this case, it has occurred to me that the apparatus, by retaining to the system the blood contained in the arm, and preventing subsequent loss, contributed largely to success. The patient's condition was certainly such as forbade the loss of any great quantity of blood. None of the sequelæ attributed to the use of the apparatus occurred, such as excessive capillary oozing and sloughing of the flaps.

Case II.—Operation at Bedford Street Hospital, for removal of index-finger with metacarpal bone. A. S., æt. 32, German, twelve weeks previously had wounded index-finger with shoemaker's knife; sloughing of soft tissues, with necrosis of phalanges and metacarpal bone, supervened. Apparatus was applied, the narrow constricting band surrounding the middle of the forearm. The tissues were rendered bloodless, and the operation, which was tedious, owing to the condition of the parts and the desire to save as much of the hand as possible, was performed. Two vessels required ligation. After the removal of the constricting band, considerable capillary oozing took place, which was controlled by application of cold water. The parts were approximated by wire suture, and lint, wet with carbolic oil, was applied. The parts healed rapidly.

As stated above, impairment of sensation and motion in the hand followed the application of the apparatus, and persisted until the tenth day. Nothing was done to relieve it, and it spontaneously disappeared.

If we can reason from the facts in this case, it would appear that paralysis follows application of the narrow band as well as of the tube, but that, owing to the distribution of the pressure over a greater surface, the nerves are less affected and sooner regain their normal powers.

PYÆMIA IN THE HORSE.—Dr. Crombie reports (*Indian Medical Gazette*) a case of this disease occurring in a horse subsequent to an injury to the foot. The sore became phagedenic, the animal feverish, and at last gangrene and separation of the foot took place, followed by death. The post-mortem examination showed multiple abscesses, varying in size from a marble to a billiard-ball, scattered through the lungs and pleura, and in the former locality surrounded by a pneumonic condition. No abscesses were found elsewhere in the body. A breaking-down cheesy mass of degenerated gland-tissue was found in the axilla corresponding to the wound.

THE ACTION OF BROMIDE OF CALCIUM AND OF BROMIDE OF POTASSIUM.—The former salt acts only on the nerves, but it produces less sedative effect than the potassium bromide, and it does not act at all on the heart, as does the latter salt.—*Guttmann and Eulenburg—Ber. Klin. Wochenschrift.*

PHILADELPHIA MEDICAL TIMES.

A WEEKLY JOURNAL OF
MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY

J. B. LIPPINCOTT & CO.,

715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, AUGUST 15, 1874.

EDITORIAL.

A MEDICAL CHARITY.

THE money which has been given in this city for charitable objects during the last two years amounts to so large a sum that we hesitate to suggest anything more at present.

We have, however, been induced—by seeing that Mr. Thomas Banting has left over \$100,000 for building a Convalescent Home, to be called the Banting Memorial—to cast some bread upon the waters, hoping it may return after many days in the shape of a handsome legacy or gift to charity. With the value of these convalescent homes our readers are as well acquainted as we are; it may be, however, that some have never noticed the complete barrenness of our city in this regard. Will not all do what they can to direct the minds of the wealthy and charitable in such direction?

AT the meeting of the Detroit Academy of Medicine, March 26, 1874, a communication was read from a corresponding member, calling attention to the explosive qualities of a mixture of carbolic acid, olive oil, and glycerin. The facts as stated were as follows: "In preparing a dressing for a contused and lacerated wound of the scalp, I poured into a four-ounce bottle about three fluid-ounces of olive oil, a drachm of liquefied carbolic acid, and two drachms of glycerin. The vial was duly labelled and corked, and carried about eight miles on horseback to the patient's house. About

thirty hours after its preparation, the vial, containing about one-half of the original amount, was standing upon a small table, in a room of ordinary temperature, surrounded by vials and sundry other articles,—among them a lighted kerosene lamp,—when a gentle explosion occurred, blowing off the top of the vial and spreading the compound uselessly around, but doing no further damage."

THE editors of *The St. Louis Medical and Surgical Journal* propose the following conundrum in alluding to one of our editorials upon the American Medical Association: "How could the Association go to an Eastern city without an invitation?" We give it up,—contenting ourselves with stating that the last meeting held in the East was in Philadelphia, and that an invitation for 1876 has already been offered. It is a somewhat remarkable and, we may say, disgraceful fact that no other Eastern city invites the Association,—a fact, however, which shows the want of interest in the Association east of the Alleghanies.

LEADING ARTICLES.

LEGISLATION FOR THE INSANE.

IT is a curious fact in the history of American legislation, one which has escaped the attention even of De Tocqueville, that the subjects on which our legislatures have most delighted to exercise their law-making privilege have not always sprung up sporadically, as it were, but have often prevailed epidemically, and exhibited that double phasis of other epidemics,—viz., of either being confined to a narrow locality, or pervading the whole country. Among our juvenile reminiscences of the Old Bay State was the fact, as patent as any gospel truth, that no member of the Great and General Court ventured to believe that he had fully discharged his duty to the State unless he had labored for some change in the militia laws or some new regulation for the taking of alewives in Taunton River. In these latter days the favored subject of State legislation has been the rights and privileges of the insane; and it has prevailed pretty extensively. The key-note to this movement is the popular conviction that insane people who are confined in hospitals are really not insane,—at least not many of them,—and that the officers of those institutions, the family of the patient, and physicians generally, are engaged in a conspiracy to tear people from their homes and confine them in prison on the false

pretence of insanity, for the purpose of accomplishing some scheme of wickedness. The great apostle of this new gospel has become qualified for her mission by several years of duty as patient in hospitals for the insane, and she believes that half the community will ultimately get shut up, unless every State places its hospitals, the patients, officers, attendants, and directors, under the supervision and control of a permanent committee of men and women, who may enter it when they please, hear the complaints of patients, sit in judgment on the alleged offences of officers and attendants, and distribute their censures with an unsparing hand. It being understood that all concerned in the management of these institutions are utterly untrustworthy,—even the directors who are appointed by the Executive from among those supposed to be best fitted for the duty by character and social position,—the patients are to be allowed to correspond as they please, with whomsoever they please, the letters in both directions to be unopened by the officers. This woman visits the State legislatures, and, with that sort of cunning which is only increased by insanity, she appeals to women of the strong-minded sort, and to men of no minds at all, by artfully playing upon their prejudices, to pass her bill. In Maine and New Hampshire (for her operations this year have been confined to New England) she is said to have succeeded. In Connecticut and Rhode Island she failed. The people of those communities “couldn’t see it,” as the phrase is. They said, If the board of directors who have been selected for their integrity and capacity require to be watched and called to account by a special board with paramount power, then, for an equal reason, this special board will need to be watched and controlled by another board, and so on *ad infinitum*.

In this State the legislation for the insane last winter was in another direction, and not inspired by Mistress Packard. Her turn, probably, will come next. An act was passed providing for the removal to the State hospitals for the insane of all prisoners in the jails and prisons of the State found to be insane, both those who were acquitted of crime on the ground of insanity and those who had become insane after conviction. The passage of the act, as might be supposed, was strongly opposed; for the idea of turning some scores of criminals into the abodes of the insane was not a matter of pleasing reflection. A letter was addressed to the General Assembly by most of the superintendents of the lunatic hospitals of the State, declaring in the strongest terms against the passage of the act,

and advising the construction of a hospital designed expressly for this class of the insane. Miss Dix, whose word ought to be law in whatever concerns the welfare of the insane, on hearing of the project, hastened to Harrisburg and opposed it with all the fervor of her earlier years. The bill was voted down at first, but, by one of those manœuvres which politicians know so well how to use, it was brought up again, and received the requisite majority.

That many of the “criminal insane,” as they are called, should be confined in a manner very different from that of other convicts is not denied; but it is equally true that many of them need surroundings as strong and a discipline as strict as those of sane criminals. They are essentially and constitutionally criminals, their insanity being only a casual incident, rendering the criminal element in their character so much the more dangerous. They are the last description of people to be placed in intimate association with the ordinary insane, for their moral influence cannot be supposed to possess any healing virtues. In reply to this, the friends of the measure say that they are to be kept together in wards by themselves, and thus debarred from all intercourse with others. This only shows how little they know of the management of a modern hospital for the insane. Are they not to be allowed to work on the farm, or in the working-rooms of the house, to attend the service of the chapel, to witness the exhibitions or join in the amusements? If they are not to share in the privileges and appliances that characterize the present hospitals, wherein are they benefited by removal from the prisons? If safe-keeping and cleanly habits are all that their case requires, these, certainly, can be obtained as well in a prison as in a hospital. Even were it practicable and desirable to maintain such a separation,—to establish a prison within a hospital,—the result would be none the less mischievous, though in another direction. Such an arrangement implies an essential difference in the moral management. Kindness, no doubt, would be the ruling principle, but in the one case it would be marked by a lack of those indulgences proper enough in the other, and of that freedom and courtesy which distinguish the intercourse between the attendant and the ordinary patient. It needs little knowledge of human nature to see what would be the final result of establishing under the same roof and the same government two modes of management so radically different. One would soon partake of the features of the other, and the whole house would become either a prison with none of its securities, or a hospital demoralized by an intrusive and mischievous element.

Especially is this measure to be deprecated for its tendency to invest the hospital with disagreeable associations and thus increase the too common reluctance to seek its benefits. It has ever been considered as a great step gained in the cause of humanity, that it is now deemed all-important that the hospitals for the insane should be assimilated as nearly as possible to ordinary domestic abodes, and made attractive and pleasing by the little adornments of a refined taste. It has been regarded as one of the triumphs of the philanthropy of our time, that, under its benign influences, insanity has been stripped of the repulsive associations connected with it, and redeemed from the imputation of disgrace which has been so freely put upon it. Certainly, if anything is calculated to renew the old odium attached to insanity, and render its abodes hateful, it is this measure of discharging into them some of the worst elements of our prison-population.

There is another objection to this new act that ought to have had weight even with those who were disposed to make light of every other, for it is difficult to see how there can be two opinions respecting it. It is well known that our two State hospitals—one at Harrisburg, the other at Danville—are now crowded to their utmost capacity. Of course, to make room for the convicts, just so many of the present inmates will have to be discharged. We have supposed we were not behind our neighbors in true regard for the criminal classes, but it never occurred to us that their offences constituted a claim for superior privileges over those granted to the honest poor. If this is really so, then they whose sons or daughters have been sent home to make way for the convicts have only to incite them to commit some criminal offence in order to get them restored to the hospital. Enough has been said, we hope, of the mischievous consequences of this act, to convince every one not committed to it by some partisan spirit, that it is founded on a series of gross mistakes.

Another act was passed, providing for removal to the hospitals of such insane persons now in the county poorhouses as "cannot receive proper care and treatment, or are probably curable." The question is not to be asked if the hospitals have room for them, so that, of course, for every one of this description admitted, a present inmate must be discharged. Pauperism is made the ground of preference in this act, as criminality is in the other. In the matter of their support, the patients in our State hospitals are composed of two classes, viz., those who are maintained by the county to which they

belong, and those who are maintained by themselves or friends, the charge being the same in both cases. While there was room for all, all were received without distinction. At last, the applications for admission exceeded the capacity of the establishment, and some of them had to be rejected. In order to effect the greatest amount of good, the rule was adopted of taking only curable cases, whether supported by their friends or by the public. Such is the policy that has always been pursued by similar institutions in other States, in similar circumstances, simply because it is the dictate of common sense and common humanity. The friends of the act, however, favored with light not vouchsafed to common mortals, declare that this is all wrong,—that an incurable, provided that he is a pauper or a convict, should be kept in the hospital till the day of his death, rather than that a score of curables supposed to be yet endowed with ever so small an amount of worldly goods, should be treated within the same period, and restored to society. The objection to the latter—that which is to shut them out from the institutions which they have all their lives been taxed to support—is that they are able and willing to pay a trifle for their board. This circumstance, it seems, places them in the category of rich patients, and they are told to resort to the private asylums. The idea of such persons going to private or corporate hospitals would be perfectly ludicrous were it not perfectly heartless. It must have been suggested by the story of the little princess who, on being told that the people outside the palace were crying for bread, asked why they didn't eat cake. It is one of those facts in our social economy, known, we had supposed, to everybody pretending to any knowledge of this subject, that a very large majority of our insane come from the humbler classes,—from those who, by dint of industry and frugality, have acquired a trifle of property, and are thus able to meet an exigency slightly taxing their resources, without calling upon the public. This fact has been recognized all the country over, in the establishment of the State hospitals for the insane; for in every instance the price of board has been set at a very low figure, scarcely sufficient, indeed, to meet the current expense, in order that people of small means might be induced to avail themselves of the benefit of early treatment.

In many of the Western States, admission to the hospital has been made perfectly free to all, like the waters of life, without money and without price. The whole history of these institutions shows that they were not intended solely for paupers, but were also designed to meet a state of things mostly pe-

cular to our time, implied in the facts that insanity has become very common, that it occurs in a great degree among the poorer classes, that early treatment is all-important, and should be brought within the reach of people of the smallest means.

We ask the friends of this new measure what is to become of these paying patients who retire in order to make room for the paupers, and we are told that they must go to the private and other asylums that are paid for taking care of the insane. We have more respect for the understanding of these gentlemen than to suppose they clearly bear in view all that is implied in their reply, and believe it is given more to stave off an inconvenient inquiry than to meet squarely the exigency they have created. Our friend Dr. Given at Burn Brae might take in four or five, at \$18 or \$20 per week. The Pennsylvania Hospital would receive twenty, perhaps, at the minimum price of \$9, and the Friends' Asylum at Frankford might, possibly, make room for half a dozen more at the same price. The true reply to the question would be that they would be sent to their homes, whence, after exhausting the domestic patience and the domestic means, they would finally drift into the county poorhouse.

Such was the legislation of our State last winter concerning the insane. Our only hope is that those who are intrusted with the carrying out of the new laws will shrink from their complete execution, and thus mitigate the evil, until better counsels shall lead to their repeal.

I. RAY.

PROCEEDINGS OF SOCIETIES.

MEDICAL SOCIETY OF THE COUNTY OF ALBANY, NEW YORK.

SEMI-MONTHLY MEETING, MAY 27, 1874.

The PRESIDENT, DR. JOHN SWINBURNE, in the chair.

DR. WILLIAM H. CRAIG reported the following case of *puerperal convulsions treated with veratrum viride and chloral hydrate*: Mrs. S., æt. 24, primipara, married two years, of delicate constitution, frail and anæmic, was delivered of a male child weighing eight and a half pounds, March 30, 1874, after an easy and natural labor of ten hours' duration; the second stage only lasting three hours. After taking nourishing drinks, slept, breathed easy, and remained apparently quietly reposing for four hours after delivery, at which time she awoke and complained of nausea; in the act of vomiting went into a convulsion, which lasted about three minutes. Dr. Craig saw her soon after, when she had in his presence a second convulsion, which was characterized by the symptoms of puerperal eclampsia.

When the convulsive action ceased, the breathing became stertorous, with coma, which soon passed off;

unconsciousness and restlessness followed, and attendants were required to keep her in bed. Her pulse was 120 per minute, and full. She talked incoherently, and complained of headache. She had had hysterical spasm previous to marriage; a knowledge of this fact induced Dr. Craig to give bromide of potassium in twenty-grain doses every half-hour, without producing any modification of the symptoms, the convulsions occurring every fifteen or twenty minutes until six hours had transpired, when Dr. Quackenbush was called in consultation. He advised the use of veratrum viride, with chloral in combination. Squibb's fluid extract of veratrum was ordered, but in its absence the apothecary sent the official tincture. When the use of the tincture was commenced, convulsions were occurring regularly every twenty minutes; pulse 140, and full; fifteen drops of the tincture and twenty grains of chloral were given every fifteen minutes, with gradually increased doses, until nearly a drachm of the tincture and forty grains of chloral were given at a dose. In three hours $\frac{31}{2}$ of the tincture of veratrum had been given, yet the pulse remained unchanged, showing the inertness of the official tincture of veratrum. The convulsions were, however, gradually diminishing in frequency, now occurring every forty or fifty minutes, but were very severe. In four hours after commencing the tincture of veratrum Dr. Craig procured Burrows's fluid extract of veratrum, and administered gtt. 20, ten minutes after which the last convulsion occurred. In one hour thereafter he gave 20 gtt. fluid extract veratrum and 40 gr. chloral; pulse 108. In an hour and a half more gave 20 gr. of chloral and 6 gtt. fluid extract veratrum. In two hours after the combination was given the pulse was reduced to 70. The veratrum was then discontinued; the chloral was administered in from 40 to 20 grain doses until about thirty hours had transpired after delivery. The urine was then examined, and found to contain a small quantity of albumen, but no casts.

April 1, 9 o'clock A.M.—Had a quiet night; remained in a sleeping stupor, but could be aroused; had frequently taken nourishment; could answer questions, but not altogether conscious. The urine was drawn with catheter, and one-fourth grain of extract of elaterium was administered in two doses at intervals of three hours, which was followed by free catharsis. After this it was not necessary to give more medicine. The convalescence was rapid and complete. At the end of two weeks she was able to sit up more than half the time. Lactation took place naturally, and both mother and babe did well. In all, two hundred and eighty grains of chloral and forty-six drops of the fluid extract of veratrum viride and one ounce of the official tincture were given in the space of eighteen hours.

It is evident that the official tincture of veratrum is an unreliable preparation in such cases, as shown by the fact that one ounce of it was given to the patient in the course of four hours without producing any perceptible influence on the pulse, while the fluid extract of veratrum caused a decided reduction of the action of the heart upon the administration of the first dose, and in two hours diminished the pulse from 140 to 70 beats per minute. Dr. Craig said that he wished to direct the attention of the Society to the remarkable influence of the remedies combined in the treatment of a disease so fearful to contemplate, and so often fatal.

He had had occasion in an address before the Society to make the following remark: that he believed the next decade would develop many marvellous changes in our knowledge of therapeutics, in which practical medicine will become more demonstrative and less theoretical than heretofore. He thought the case presented might verify the statement made, for, according to his experience, the means formerly used in the treat-

ment of similar cases would not have saved this case from a fatal termination. It also confirmed the statement made by Dr. Squibb before the King's County Medical Society, when the use of veratrum in the treatment of eclampsia was under consideration. Dr. Squibb remarked, "The cases of puerperal convulsions reported here treated by veratrum proved to his mind that there is no fixed dose; the test must be the effect produced, and not the number of minims given."

"The tendency in therapeutics at present seems to be to get rid of the trammel of doses."

Dr. Craig continued, and said that very many cases of puerperal convulsions had been reported in the various medical journals treated by veratrum alone by numerous physicians, and quite successfully, and some fatal cases are mentioned where it seemed to him if the chloral had been combined with the veratrum a disastrous result might have been averted. Other cases have been treated by chloral alone; each remedy has its advocates. The *New York Medical Record* and the *Obstetrical Journal* contain numerous reports of cases treated by each remedy alone, but he had not seen where any case had been treated by the combination of both remedies.

If the pathology of eclampsia is considered according to the modern theory, which may be expressed in a single word, "irritation," we can then better appreciate the influence of the two remedies in controlling this disease.

Dr. Robert Burns, in a recent lecture in which he speaks of the treatment and etiology of puerperal convulsions, gives four cardinal points for guidance—viz., "1, to moderate central nervous irritability; 2, to cut off emotional irritants or excitants; 3, to cut off peripheral irritants or excitants; 4, to eliminate all complicating morbid conditions."

Dr. Radcliff, in a work recently published on disorders of the nervous system, advocates the theory that nervous irritation may be reflected to the nervous centres through irritation of the uterine nerves and excitation of the coats of the blood-vessels.

The chloral undoubtedly allays the irritation of nerve-centres, while the veratrum lessens the excitation of the coats of the blood-vessels by reducing the vascular action.

Dr. QUACKENBUSH said that the ideas expressed in reference to the cause of puerperal spasm are generally erroneous. It is generally supposed to be in some way connected with the kidneys. Albuminuria is often present in some stage of pregnancy or labor. Why it should appear at this time is not understood. The pressure of the gravid uterus on the ureters or renal vessels is not now the accepted theory. Fibroids distending the cavity and pressing on the kidneys do not produce it.

Barnes is of the opinion that the kidneys being overtaxed with eliminating excrementitious matter is the cause. We may have symptoms in the early stage without convulsions. Some think it is caused by nervous irritation. Whatever the cause may be, the consideration is to remove the great central irritability. Under these circumstances it is considered best to bring about labor as speedily as possible. The practice is not to use force; if necessary, rupture the membranes and wait for nature.

Chloroform is recommended, not to arrest spasms, but to prevent them. It is important to remove external excitants, that is, to exclude noise, light, loud talk, etc., and then use chloroform to blot out memory and render it oblivious to these circumstances. Again, remove all peripheral excitants; use no cathartics or blisters or cold water dashed into the face. By using veratrum and chloral we regulate the circulation and quiet the nervous system. Dr. Quackenbush was of the opinion

that chloral served a better purpose than chloroform. The veratrum diminishes the great action of the heart and circulatory system; when this is left unabated it facilitates the absorption of the poison carried through the circulation.

Dr. JAMES S. BAILEY said that at the recent meeting of the Pennsylvania State Medical Society this subject was discussed through reference to it by Dr. Atkinson in a paper in which he reviewed the progress of gynecology and obstetrics during the past year. The doctor advocated the use of chloral strongly. Distinguished physicians joined in the discussion, and among them Prof. Gross, who insisted that the dose must be at least thirty grains repeated frequently. Others employed it by the rectum when the stomach could not tolerate it.

Dr. Bailey also referred to a recent article appearing in the *Western Lancet* by Dr. Deane, who urges the advantages of chloral strongly, after an extended use of it. When eclampsia was suspected, fifteen grains of chloral were administered every twenty minutes until sleep was produced. He further recommended the use of the drug for thirty-six hours after labor is finished.

One case was mentioned in which two hundred and fifty grains were used in thirty hours, with the happy effect of controlling the convulsions and facilitating recovery. The patient was delivered with instruments. Her urine was impregnated with albumen, filling a test-tube half full after delivery; in forty-eight hours thereafter it had entirely disappeared.

The PRESIDENT inquired what proportion recovered when treated with these remedies.

Dr. W. H. CRAIG said that he had not noticed similar treatment in any of the medical journals, and inquired of Prof. Quackenbush if he had.

Dr. QUACKENBUSH said that he had not. He had, on the same day that Dr. Craig's case occurred, been called to see another case of puerperal eclampsia with Dr. Fowler. They had used two grains of chloral every half-hour. The patient made a good recovery. In this case spasms came on before delivery.

Dr. LORENZO HALE mentioned a case which had recently come under his observation, of protracted labor. He had found it necessary to give in the course of three days, to relieve the nervous irritability, between six and eight ounces of chloroform by inhalation. He had no doubt but that a considerable quantity was lost by evaporation. During this interval he had given, in addition, three hundred grains of chloral, in doses of fifteen to twenty grains at short intervals. Consultation was summoned, but the patient died. Dr. Vanderveer made the post-mortem examination. The uterus was found well contracted. On opening the stomach, a peculiar odor resembling chloral was perceptible, and the coats of the stomach separated like wetted brown paper. The impression was that the chloral had been instrumental in producing this effect.

Dr. SWINBURNE referred to the case of a girl who had died mysteriously, in Hudson. It was suspected that she had had an abortion produced. Her stomach was obtained and examined by a chemist, who found no cause for death in its contents. The same condition was noticed in this case. Dr. Swinburne was of the opinion that this condition was caused by a post-mortem change. This same stomach was submitted for examination to physicians in New York City, Dr. Clark and others, who thought the gastric juice had produced the softening of the coats.

Dr. VANDERVEER, when asked if he had ever noticed a similar condition of the stomach, said that he had, in the person of a besotted man who had died with delirium tremens.

Dr. J. B. STONEHOUSE spoke of the use of chloral in insane asylums, and in the event of death no unusual condition of the stomach had been found. He

mentioned one case where a patient had taken forty grains per day for at least seven months without producing any derangement of the stomach. So noticeable was the fact that it had suggested the propriety to the attending physicians of using chloral for indigestion.

Dr. JONES inquired whether any member had had experience in reference to the internal use of chloroform.

Dr. JAMES S. BAILEY said that he had, and had found it particularly serviceable in relieving acute spasmodic pain. He had frequently given teaspoonful doses, repeated in half an hour if necessary. Its first effect was to stimulate like alcoholics, and then came drowsiness and sleep. He had frequently seen patients while coming under the effects of it talk incoherently, but this would soon subside, and be succeeded by quiet repose.

Dr. F. C. CURTIS reported the following case of *tuberculous ulceration of the larynx*, and presented the pathological specimen of the same.

G. S., æt. 28, laborer, was first seen about three months before death. He came to the office complaining mainly of trouble in his throat,—did so at the earnest solicitation of his friends. He had been hoarse for a year back. This came on gradually, and for some time he had not been able to speak above a whisper. There was never much pain in the part. He had been engaged in herding cattle at West Albany yards, and the cause assigned for his throat-affection was shouting to the cattle while driving them.

His father said that he had been very intemperate in the use of his voice, straining it without reason. The same lack of care had been observed in other things: he had exercised violently, and then sat in a cool place chilling his body, or had drunk immoderately of cold water, and sometimes of alcoholics. He had not been excessive, however, in the use of the latter.

His father stated that he had had a cough for several years past, particularly after a slight exposure. For the last three years this had been more steady. He had been irregular as to the time of taking food.

Still, in spite of cough and dysphonia and utter disregard of health, he had, until recently, been a pretty strong fellow, and had never had any severe sickness. He had had occasional pain in the chest, more of late, which was not severe. He had, too, lost strength somewhat, and emaciated. Expectoration was and had recently been somewhat abundant. No night-sweats.

Having come principally on account of his throat, it was examined with the laryngoscope. There was found moderate œdema of the aryteno-epiglottidean folds on both sides, extending pretty uniformly around the glottis. The epiglottis was not affected, and a very good view of the cords throughout, with their surroundings, could be obtained. A large ulceration was found on the right side, posteriorly, over the arytenoid cartilage, affecting the posterior third of the vocal cord, but having its centre above it in the ventricle. Phonation was prevented by the inability to bring the two vocal cords in contact, from loss of substance and circumscribed action of the left cord. The ulcer was quite deep, but not abrupt; nor was there thickening or granulation of the edges. Outlines were ragged. No apparent discharge. Surrounding it were congestion and moderate œdema, but no other lesion was discovered. Anæsthesia of the throat generally was somewhat noticeable, as the first examination was readily borne.

Examination of the lungs showed consolidation at both apices, and fluid in the bronchi. His general appearance was fair.

Treatment was directed solely to his general condition. Tonics and cod-liver oil were given, and directions as to care of himself. He came to the office at irregular intervals for a few times, no particular change

being noticed. He then ceased to report himself, and occasional word was brought that he was failing. It is probable that he took but little care of himself. He gradually failed in strength, and night-sweats, very profuse, with severe hectic fever, came on.

Called to see him near the end of February, six weeks before he died. Found the affection of the lung had extended very rapidly, and was far advanced from the condition of a month before. Mucous and submucous râles were heard all over both lungs, and there was evidence of cavities forming at both apices. Cough was harassing and constant, expectoration being very abundant. He had but little pain, but was unable to sleep from cough and sweating at night. The latter was checked somewhat by sulphuric acid and hyoscyamus. The bowels were not affected. There was no change in throat-symptoms. From this time the disorganization of the lungs advanced rapidly. He emaciated, and œdema of the face and extremities came on. He kept about the house to the last, and rode down town in a car a fortnight before he died. He was perfectly conscious to the last.

Died April 7.

Post-mortem twenty hours after death. Body much emaciated, and extremities œdematous.

Thorax.—Both lungs were bound by very firm adhesions to the chest-walls for the upper third, lung-tissue tearing up on attempting to separate them. This was more extensive with the right lung, and at one point there was a ring of adhesions two inches in diameter, into which a cavity of the lung had perforated, matter and air oozing out as the lung was removed, at this point, which was under the scapula.

There was a small amount of effusion into both pleural cavities.

There were deposits of tubercles throughout both lungs, studding them so abundantly as almost to solidify the tissue in parts. This was mostly of miliary size; but there were masses of the size of a hazel-nut. In the lower lobes there were recent gray tubercles; farther up they were caseous at the centre and at the upper fourth of both lungs, but more of the right. There were very many cavities, some being filled with caseous matter, simply as if just transformed from tubercle, others containing more or less purulent matter. Some were quite large, with ragged sides, and filled with pus and mucus. Mucopurulent matter exuded from the lungs on section, extensive tracts not being aerated. Only a small portion of the lower lobes along the anterior edges crepitated normally on the right side, and the edges of both lower and upper of the left.

Examination of the larynx disclosed a large ulcer on the right side, at the posterior extremity of the vocal cord, ventricle, and false cords. It was quite deep, extending into the soft tissue above the cricoid cartilage. Anterior to the arytenoid it extended deep down towards the wing of the thyroid. It did not involve much of the cord, not cutting entirely across it, though a sinus ran in back of it. The outline was irregular, but the sides were pretty smooth. A spherical ulceration of the mucous membrane surrounded this, the whole being about the size of a five-cent piece. Of this, the ulcer proper occupied rather more than half.

Directly opposite this ulcer, at a corresponding point of the left side, was a still deeper ulcer, but not affecting the vocal cord by ulceration even of its mucous membrane.

It was in the ventricle, and was a mere slit in its long diameter, a third of an inch in length. It was on the line of the superior border of the cricoid cartilage posteriorly, extending back nearly to it. It could only be seen by separating the parts, being closed and invisible in a natural condition of the tissues. Extending

upward from it was a considerable superficial ulceration of the mucous membrane. The entire inner surface of the larynx was swollen, the cords, both true and false, being thickened so as to be hardly recognizable, and almost obliterating the ventricles. The anterior surface of the larynx was not so much affected, and the epiglottis was hardly at all thickened.

There was considerable œdema of the tissues between the cricoid and thyroid cartilages, probably induced by the ulcers extending deep into them.

In the trachea there were a few quite superficial ulcerations or erosions of the mucous membrane. In one point only, low down towards the bifurcation, there was one that appeared to go nearly down to the cartilage.

The heart and the abdominal organs were healthy.

A few words in regard to this somewhat rare affection may, perhaps, not be out of place. First, in regard to the propriety of the term "tubercular ulcer." It is a question in debate whether the morbid process by which these ulcers exist is really tubercular,—*i.e.*, whether they are due to the deposit of tubercle in the tissue, which, breaking down, causes a destruction of tissue, or whether they are simply the results of inflammatory action. Apart from any heterogeneous deposit, Virchow says tuberculous ulcers do actually originate from miliary tubercles. The absence of them so frequently, which leads other observers to deny altogether their presence in connection with ulcers, he explains by the perishable nature of these deposits. He asserts that he has found them himself.

Rindfleisch allows that they may be developed from tubercle, led to do so partly by the assertion of Virchow, and partly from having himself observed in microscopical sections vertically through ulcers, clusters of cells situated well below the surface, in the midst of connective tissue still intact, which remind him strongly in their behavior of miliary tubercles. "These tubercles, however," he says, "are so sparingly disseminated and appear so insignificant in comparison with the inflammatory infiltration of the ulcerated surface itself, that I would only regard them as a pledge of the connection of the morbid changes with constitutional tuberculosis. At most they could only be raised to the dignity of permanent inflammatory irritants." (New Sydenham Publications, vol. liv.)

Niemeyer seems to believe in the tubercular origin of these ulcers. He says the severity of the cough cannot account for them, for it is often more severe in mere bronchial affections. Neither for the same reason can they be said to originate from foul acrid secretions from large cavities.

Their anatomical appearance, too, as described by him, indicates this opinion. "We first observe," he says, "gray, round granules the size of a millet-seed, which turn yellow, soften, and disintegrate, leaving a small round ulcer.

"Fresh deposits in the vicinity occur, and the resulting ulcers run together, forming an irregularly-shaped loss of substance. More frequently, though, we first notice a yellowish discoloration, which the microscope shows to be an infiltration with small cells.

"The mucous membrane becomes relaxed, and a shallow ulcer follows, which may afterwards extend very deep."

Türk, of Vienna, whose authority in affections of the larynx is received with great respect throughout Germany, though he has now been dead several years, says that deposit of tubercle is not often the direct cause of these ulcers, yet that it is beyond a doubt that a certain number of them are due to it. The most common cause is catarrhal and follicular inflammation.

Cohen, of Philadelphia, is very doubtful as to tubercle being deposited here, and would regard the small white pin-head points described as miliary tubercle as,

in most cases, enlarged follicles. (Cohen, Diseases of the Throat, p. 357.)

Other observers utterly refuse to allow that tubercle is present or participates in these ulcers.

But it is not necessary to quote the opinions of a long list of authorities on this subject, which is of no great practical importance in the direct consideration of these ulcers. It has occurred to me, however, that it might be a good field to study tubercle itself, and might throw light on the now widely-discussed pathology of this heterologous formation.

The general opinion held by most of the best authorities seems to be that a limited number of the ulcers occurring in the larynx with phthisis are caused by a direct deposit of tubercular matter.

Ulcers may occur in the larynx from a variety of causes. Besides the one under consideration, there are those due to syphilis, to inflammation of the mucous membrane, either catarrhal or of the glands, to diphtheria, cancer, etc. The diagnosis of the ulcer of tuberculosis from all the rest is particularly desirable, inasmuch as the treatment is quite the opposite from most of them: while other ulcers may be made to heal only by severe treatment,—cauterization, perhaps,—these are to be let alone, or to be soothed by sedatives and protectives. But the appearance presents little that is characteristic, so far as I have been able to learn. Any of them may be superficial, or deep and extensive. There are, however, certain guides to a satisfactory conclusion.

The ulcers of cancer are accompanied by lancinating pain, the absence of which may exclude it, also the locality of the cancer-ulcer, which affects preferably the anterior portion of the larynx when affecting it alone.

The most common variety of cancer met with here, according to Rokitsky, is the epithelial, this being a favorite location for its development. The diagnosis lies mostly between it and syphilis, which it resembles more than other ulcers.

Between tubercular and syphilitic ulcers the diagnosis may be, in a measure, reached by the locality. Syphilis attacks most commonly the epiglottis, and hardly ever the vocal cords. Tubercular ulcers are found more at the posterior portions of the larynx, affecting the false and true cords, and the vestibule, rarely attacking the cartilages, and seldom attended with much œdema, both of which occur with syphilitic ulcers. Trousseau says that a dusky color of the membrane is diagnostic of syphilis. Aphonia is more complete in tubercular than in syphilitic ulcerations.

An ulcer seated on the posterior portions of the larynx, attended with only moderate œdema, causing more or less complete aphonia, lasting perhaps for a long time without producing great destruction of tissue, the pain of which is of moderate severity or but little noticed, and finally coexisting with phthisis of the lungs, may be called a tubercular ulcer. I think this is about a fair picture of it. Only a small portion of the cases of sore throat with phthisis are due to ulceration, the existence of which can only be made certain by the laryngoscope.

A word only in regard to treatment. I think but little is called for locally. The ulcers are very seldom of themselves the immediate cause of death, and probably only by opening into the œsophagus. Their tendency is, after advancing to a certain point, to remain stationary, producing but little serious inconvenience. Such is the result of my own limited observation of them. The general treatment of phthisis will, of course, be given. Locally, only such remedies are called for as will relieve them of irritation. Cough should be combated, as an evident irritant. Morphia is sometimes applied locally. Nitrate of silver in solution is said by Niemeyer to alleviate the cough, a bit of

sponge being dipped in it and squeezed over the entrance to the glottis. Cohen speaks of inhalations of carbolic acid; but I believe that when no great disturbance is caused by the ulcer no local treatment is called for; nothing but general building up of the system, which we always attempt to effect in consumption of the lungs.

GLEANINGS FROM OUR EXCHANGES.

INSTRUMENT FOR DETERMINING THE CALIBRE OF THE URETHRA AT ANY GIVEN POINT.—Dr. F. N. Otis, of New York, communicates to the London *Lancet*, July 11, a description of an instrument devised by himself and intended to serve as a gauge of the normal urethral calibre, and also to measure that of strictured portions of the tube. The instrument, a drawing of which accompanies Dr. O.'s communication, is practically a sound, having a gauge at its distal extremity and an indicator near the proximal or external end.

"It consists of a small straight canula (No. 8, F) terminating in a series of short metallic arms, hinged upon the canula and upon each other. At the distal extremity where they unite, a fine rod, running through the canula, is inserted. This rod (which is worked by a stationary screw in the handle of the instrument), when retracted, expands the arms into a bulb-like framework 10 mm. in circumference when closed, and capable of expansion up to 40 mm. A thin rubber stall drawn over the end of the closed instrument protects the urethra from injury, prevents access of secretions to the interior of the instrument when expanded, and completes the bulbous appearance of the dilating apparatus.

"When this instrument is introduced into the urethra and expanded up to a point recognized by the patient as comfortably filling his urethra, the hand on the dial will indicate the calibre of the canal at the point occupied by the bulb; moving this gently backwards and forwards, the tactile sense of the operator, by the aid of the screw at the handle, will give a fair knowledge of the capacity and condition of the presenting canal."

DEATH FROM CARIES AND DISLOCATION OF THE ODONTOID PROCESS (*Lancet*, July 11).—A post-mortem examination was made recently at St. Thomas's Hospital in the case of a patient, a young man, who had suffered for some months with soreness in the neck, accompanied by stiffness and difficulty of motion. Within the three weeks previous to his death he began to experience pain in the neck, especially on bending the head forward. This was followed shortly after by numbness in the left hand, and later, in the arms and legs with a pricking sensation. His breathing soon became difficult, his face blue, and he died on his way to the hospital.

At the post-mortem examination, on the body being opened, all the internal viscera were found to be quite healthy; and, on opening the skull, the brain was also found perfectly healthy; but, on close inspection of the interior of the skull, the odontoid process of the axis was found filling up the foramen magnum, having ruptured the check and the transverse ligaments, perforating the meninges of the cord, and pressing upon the spinal medulla. The lower part of the medulla oblongata at the seat of pressure was softened and pulpy, and a collection of matter had found its way between the membranes and the cord. The occipito-atloid articulation of the left side was carious and entirely disorganized, and occupied by an abscess cavity, which had probably burst at a point where the odontoid process had perforated the dura mater. The posterior part

of the anterior arch of the axis, as well as the anterior edge of the foramen magnum, was also carious.

ELIMINATION OF ALCOHOL.—In *The Practitioner* for July, Dr. Anstie gives the results of final experiments made by himself and Dr. Dupré, with the view of ascertaining as nearly as practicable whether alcohol to any appreciable extent escapes unchanged from the body of an animal which has ingested it. The animals chosen for experiment were dogs, which approach most nearly to man in their capacity for resisting the effects of alcohol. The experiments were performed by the aid of a Pettenkofer's chamber, in which the animal was confined, while a current of air passing through the box was condensed in water. By this means all its excretions could be obtained and analyzed.

The result of a series of these most carefully conducted experiments, including one where the entire animal was subjected to a sort of "destructive distillation," proves conclusively that within certain limits alcohol ingested by an animal becomes totally metamorphosed within the system, the percentage eliminated as such being almost inappreciable. Dr. Anstie concludes that quite six hundred grains of absolute alcohol can be disposed of daily within the organism of an adult male without any perceptible injurious effect upon the bodily functions.

If alcohol be a force-producing food, it is probably of great value in that capacity, on account of the rapidity with which its transformations take place.

It is certain, however, that beyond a certain dosage, varying for the individual, it becomes a violent narcotic poison, the more dangerous that it cannot be eliminated to any considerable extent.

If alcohol does not disappear by oxidation, it must undergo some as yet quite unknown transformation, after which it must escape unrecognized in the excretions.

If alcohol, however, be indeed oxidized, and yet does not beget force which can be used in the system, this would be the strangest possible discovery. Considering the very high theoretical force-value of the six hundred to eight hundred grains of absolute alcohol which millions of sober persons are taking every day, we may well be hopeless of any reasonable answer to the question, Why does not this large development of wholly useless force within the body produce some violent symptoms of disturbance?

CASE OF PHTHISIS WITH UNCONSCIOUSNESS FOR FIFTEEN MONTHS.—Dr. B. F. Scull reports, in a recent number of the *American Medical Weekly*, a case in which a man who had been suffering from severe bronchitis, with symptoms of incipient phthisis, for several months, fell into a condition resembling catalepsy. Although eating and drinking whatever was offered, he seemed entirely indifferent as to the character of the food, and wholly unconscious of his surroundings, of his condition, of what he was doing, or of what was being done for him. His fæces were passed into a diaper, and it was necessary to keep him cleansed without any co-operation on his part.

After remaining in this condition for some fifteen months, he suddenly recovered consciousness, but fell into a rapid decline and died a year later.

DEEP INJECTION OF CHLOROFORM FOR THE RELIEF OF TIC DOULOUREUX.—Dr. Roberts Bartholow communicates to *The Practitioner* (June, 1874) an account of several cases of this painful affection treated successfully by hypodermic injections of chloroform.

The infra-orbital branch of the nerve was the seat of the tic in the cases reported, and Dr. B.'s operation consisted in passing the needle under the upper lip in the direction of and near to the infra-orbital foramen, and

then injecting from ten to twenty minims of pure chloroform. Considerable pain at first ensues, followed by a feeling of numbness and anaesthesia of the parts into which the chloroform diffuses. A puffy swelling quickly forms at the site of the injection, and an induration which lasts for several days follows. One very severe case operated upon in this manner gained relief from one injection covering a period of months.

POISONING BY COAL-GAS.—Dr. William Taylor, in a communication published in the *Edinburgh Medical Journal* for July, gives a number of interesting cases of this form of poisoning, from his own practice and that of others, including quotations from a monograph by Dr. Tourdes, of Strasburg. From the latter Dr. Taylor quotes the following list of characteristics, with which his experience agrees:

Post-mortem characteristics of poisoning by coal-gas: 1, coagulation of the blood; 2, its deepened tinge; 3, extreme brilliancy of coloration of pulmonary tissue; 4, abundance and nature of froth in the air-passages; 5, intensity of cerebral congestion; 6, engorgement of vertebral nervous system and extravasation of coagulated blood in the spinal column; 7, vivacity of injection of the mucous surfaces at base of tongue; 8, occasional rose-colored patches on thighs.

The morbid phenomena accompanying the action of the gas are thus classified in the order in which they occur:

1, insidious invasion—premonitory symptoms of variable duration; 2, headache and vertigo; 3, nausea and vomiting; 4, affection of intellectual faculties, involving absolute loss of consciousness; 5, general debility, prostration of strength, partial paralysis, convulsions; 6, phenomena of asphyxia, appearing slowly, but complete and predominant during the last moments of life.

GALVANISM IN AMENORRHOEA.—Dr. Jas. Whittaker (*The Clinic*, July 25) relates a case of obstinate amenorrhoea occurring in an otherwise healthy female aged 22 years, in which, after all other means of relief had failed, the interrupted current from a battery of twelve elements induced the menstrual discharge. In applying the current, the positive electrode was placed over the fundus uteri externally, and the negative, a fine gold-pointed wire, was introduced within the cavity of the uterus.

TREATMENT OF ERYSIPELAS BY SUBCUTANEOUS INJECTION OF CARBOLIC ACID.—Dr. Aufrecht practised injections of carbolic acid in doses of 0.60 centigramme in ten cases. Not only were the erysipelatous swelling and redness rapidly dissipated, but the temperature, pulse, and general health were remarkably improved.—*Centralblatt*.

MISCELLANY.

FOUNDLINGS.—The proportion of foundlings in France is rather considerable, so much so that the Council General of the department of the Rhône offer a prize of \$400 for the best essay on Foundlings. The following points are simply recommended to authors, though the Council grant them full liberty. 1. Causes of the abandonment of children. (a) What are the results obtained by statistics? (b) Do social, political, and religious conditions act upon the number of foundlings? (c) Were children left to public mercy among the ancients? Can the time be fixed when the forsaking of children, exceptional in antiquity, took a great propor-

tion, and under what social and religious influence has such increase taken place? 2. By what measures could the number of foundlings be diminished? What becomes of them? Establish a parallel between the moral and physical conditions of foundlings and other children. 3. By what means could foundlings be morally and physically improved? How could mortality among them be diminished? And how could their ultimate fate be ameliorated? 4. Which is the best manner of taking care of them? What has been the result of the suppression of turn-stiles? And how should we view such suppression?

TO INCREASE THE ADHESIVENESS OF GUM ARABIC.—Concentrated solution of gum arabic as a mucilage possesses the disagreeable property, when spread upon printing or other paper not strongly sized, of penetrating them to transparency and in spite of this not making them adhere to other paper. Paper cannot be attached to common pasteboard, nor wood to wood. Paper pasted with mucilage on metallic surfaces usually falls off soon. The use of gum as cement for glass, porcelain, or earthenware, etc., is entirely impossible.

All these disadvantages of mucilage are remedied when an aqueous solution of sulphate of aluminium is added. For two hundred and fifty grammes of the concentrated gum solution (prepared with two parts of gum and five of water), two grammes of crystallized aluminium sulphate will suffice. This salt is dissolved in ten times its quantity of water, and mixed directly with the mucilage, which in this condition truly deserves the name of *vegetable glue*. Solution of alum serves the same purpose, but far less efficiently.—*Druggist's Circular and Chemical Gazette*.

NOTES AND QUERIES.

TO THE EDITOR OF THE PHILADELPHIA MEDICAL TIMES:

I see by your issue of July 25 that Dr. W. B. Atkinson claims priority over Dr. Bernardy in the use of *chloral hydrate* for the mitigation of *puerperal eclampsia*. He claims to have used chloral for this purpose in October, 1871. My partner, Dr. H. A. Schell, gave chloral to Mrs. Buck for *puerperal eclampsia* March 9, 1871. We subsequently gave it to Mrs. Sone, a primipara, for this purpose, September 26, 1871,—sixty-grain doses by enema till consciousness was restored, then gave twenty grains by the mouth every two or three hours as long as any nervousness remained. You will observe, therefore, that we have two cases anterior to the date of Dr. Atkinson's case in October.

Very respectfully,

H. B. MALONE, M.D.

GALLATIN, TENNESSEE, July 30, 1871.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY, FROM AUGUST 4 TO AUGUST 10, 1874, INCLUSIVE.

HARTSUFF, A., ASSISTANT-SURGEON.—Leave of absence extended twenty days. S. O. 57, Military Division of the Missouri, August 4, 1874.

WIGGIN, A. W., ASSISTANT-SURGEON.—Assigned to duty at Fort Stevens, Oregon. S. O. 98, Department of the Columbia, July 29, 1874.

WOODRUFF, E., ASSISTANT-SURGEON.—Leave of absence extended three months. S. O. 168, A.G.O., August 3, 1874.

McLAREN, A. N., SURGEON.—Died August 1, 1874, at Boston, Mass.

PHILADELPHIA MEDICAL TIMES.

SATURDAY, AUGUST 22, 1874.

ORIGINAL COMMUNICATIONS.

AN INVESTIGATION INTO THE ACTION OF VERATRUM VIRIDE UPON THE CIRCULATION.

BY H. C. WOOD, JR., M.D.,

ASSISTED BY JOS. BERENS, M.D.*

PART I.—VERATROIDIA.

Section A.—General Action of the Circulation.

AS is well known, some years since I published a physiological paper upon the alkaloids of veratrum viride. This paper, although correct so far as it went, was by no means complete in regard to the therapeutically most important portion of the subject. This lack of completeness arose from two sources. In the first place, the study was my first attempt at this sort of original work, and in the second place, my supply of the alkaloids was exhausted before the investigation was complete. Ever since, I have wished to carry out the work commenced, but have been unable to obtain more of the alkaloids until recently. As great stress has been laid in a certain quarter upon the fact that the alkaloids which were previously employed were not chemically pure, and as, in some of the experiments hereafter detailed, the poison used certainly was impure, a few words of introduction seem necessary. The researches of Bullock and of Mitchell appear to have positively determined that there are two alkaloids in veratrum viride, and only two. It is a comparatively easy task to separate these alkaloids from each other, but a most difficult if not an impossible one to free completely the separated alkaloids from adherent resin. This resin being inert is a chemical but *not a physiological* impurity, and therefore its presence in greater or less amount only affects the results of experiments in regard to the dose. The alkaloid containing twenty per cent. of resin must, of course, be given in doses twenty per cent. larger than the pure alkaloid, but, this being done, the results are identical. These facts rest upon experimental as well as chemical grounds, the purest alkaloid obtainable having produced, when given in proportionate dose, exactly the same symptoms as were caused by impure specimens.

In my first investigation the following experiments were made to test the action of veratroidia upon the circulation in the uninjured animal.

Experiment I.—(Exp. 18.)—A moderate-sized mongrel dog.

TIME.	DOSE.	PULSE.	PRESSURE.	REMARKS.
0	gr. 1	108	120-150	Pressure sometimes as low as 110, and as high as 160.
5		106	55-80	Into peritoneal cavity.
7				Pressure sometimes rises to 95. Vomiting. A convulsion.

* Dr. Wood took part in all experiments, and is responsible for their accuracy, as well as for the plan of the investigation and all deductions made. Dr. Berens did a full share of the experimental work.

TIME.	DOSE.	PULSE.	PRESSURE.	REMARKS.
10	m.			Dog apparently dead.
12	"	50	110-150	Several howling, laborious breaths, then quiet. The individual beats of heart very powerful, driving mercury through 40 m.
15	"	140	175-195	The breathing for the last five minutes has consisted of a few paroxysms of half a dozen convulsive respiratory efforts. The pressure has been as high as 210.
16	"	0	0	The mercury fell in the tube almost instantly. Dog dead. The autopsy showed brain and medulla congested with dark blood; right side of heart enormously congested and swollen; left side nearly normal; venous system everywhere gorged; blood very dark.

Experiment II.—(Exp. 19.)—Terrier dog.

TIME.	DOSE.	PULSE.	PRESSURE.	REMARKS.
0	gr. ½	112	120-160	Hypodermically.
5		112	120-160	
10		104	75-90	
15		84	75-90	
17				Dog vomiting violently.
20	"	68	90-105	Dog still vomiting. No purging or convulsions, but a slight twitching of muscles.
30		76	90-105	Some convulsive movements.
35			110-120	Dog quiet; not vomiting (hence, probably, arterial pressure increased).
40		96	70-90	Immediately after a severe paroxysm of vomiting.
40½			90-105	
40¾	"	115-120		Pressure rising sometimes to 125.
41		90-105		Directly after a violent opisthotonic convulsion, which has just ceased.
45		140	115-120	Dog quiet.
50		140	100-115	Rarely rising to 130.
53				Dog was unfastened, and pushed off the table; he fell relaxed and stone-like, but in a little while strove to get up, and, struggling violently, slowly progressed forward, scarcely lifting his belly off the ground. Upon being seized a few moments after, he had a violent convulsion, which was quickly followed by total unconsciousness; touching the eyeball producing no effect. Breathing had apparently ceased; pulse very feeble. After lying quiet for some time, he slowly returned to consciousness.
65	gr. ½	104	155-175	Dog breathing well again.
80		104	95-105	Dog has not moved for fifteen minutes.
				Injected into peritoneum. Dog showing no signs of life when struck or hit.
85			80-90	Going up to 100.
90				Vomiting.
95	"	108	105-115	
110		104	90-100	Dog now untied, and allowed to lie undisturbed. He died in a few minutes.

In commenting upon these experiments I used the following language: "The action of veratroidia upon the heart seems more difficult of interpretation. In Experiment 18 there was a marked depression in the force and rapidity of the blood-movement, lasting for ten minutes. At the end of this time death by asphyxia was rapidly produced, and the circulation underwent a curious change. The pulse, in a moment, was reduced to a mini-

mum in rapidity, but the individual beat became endowed with four times its normal force; the pulse then rapidly rose to one hundred and forty,—twenty beats beyond its pristine number; the individual heart-contractions becoming much more normal, but the arterial pressure rising far above what it had been previous to the administration of the drug. Then very rapidly the mercury fell, and in a moment the heart was stopped, and all was over.

“I think the most probable explanation of this curious phenomenon is to be looked for in the sudden cessation of the respiration, and the consequent rapid production of asphyxia. The increase in the force and rapidity of the heart’s action was most probably due to the overpowering of the specific action of the veratroidia by that of the carbonized blood. In his admirable ‘Physiological, Pathological, and Anatomical Researches’ (p. 33), Dr. Reid has a paper on the ‘Phenomena of Asphyxia,’ from which the following is extracted:

“ ‘When the animal was breathing freely through the tube in the trachea, was quiescent, and when the blood was fully arterialized, the range of level in the mercury in the tube seldom exceeded half an inch, sometimes not so much. When the stopcock was shut, no change took place in the range of the mercury during the first half-minute; generally before the end of the first minute the animal had begun to struggle, and the range greatly increased, rising during each attempt at expiration, and during the struggling of the animal. In some experiments the range of mercury amounted to about nine inches, and in one experiment to ten inches.

“ ‘In a third experiment, the pulse was 100 before the stopcock was turned; at the end of one minute the blood was getting dark, the animal was beginning to struggle, and the pulse was 120. During the second minute the animal struggled violently, and the pulse could not be reckoned. At the end of two and a half minutes the animal ceased to struggle, the respirations were few and heaving, and the pulse was 78.’

“In Experiment 19, the primary period of depression ended in a gradual increase in the frequency and force of the pulse, which had risen to 140 instead of 112 in a minute,—the number before its administration,—but had not quite regained the force which it had had previous to the use of the drug, when a period of collapse and apparent death came on; after reaction from this, however, the circulation more than regained the power which it had at first. A further dose of the veratroidia was followed by the same depression and subsequent rebound of the circulation. The indications do not, in this case, point so clearly to the accumulating carbonic acid as the cause of the secondary arterial excitement, but I cannot help believing it has something to do with the latter.”

In the present investigation, the first experiments with veratroidia were directed to discovering whether the effects obtained in the study of Mr. Bullock’s alkaloid are constant. These experiments are as follows:

Experiment III.—Small stout dog.

TIME.	DOSE.	PULSE.	PRESSURE.	REMARKS.
		140	110-115	Respiratory efforts frequent and deep, during which a maximum and minimum pressure was attained of 100-125. Injected into femoral vein.
0	gr. 1-40			
10			10	
30			0	
45				Pressure rising; the respiration profoundly affected; vomiting. Respiration ceased; the pulse very weak and quivering; blood very black. Respiration resumed.
1			140	
1¼			165	
1¾				
2			10	
3		114		Pulse very weak. Clot.
6		198	200	Pressure has been up to 210. Clot.
7				Pressure sometimes falling as low as 100, and rising to 145. The respiratory efforts three in a minute, and shallow and gasping in character.
11			115-130	Individual beat fifteen cent. Respirations but two to the minute.
12	gr. 1-40	100	90-110	Respirations but one to the minute. Into femoral vein. The pressure fell instantly.
21		84	80-85	
21¾				
21¾			40	
22¼			85	
22¾				
23¼			110-120	
26		165	95-100	Pressure rising to 115 and falling to 90. Respiration feeble and slow.
35				Heart instantly arrested. The organ was flabby; responded feebly to stimuli, and filled with black blood.
	gr. 3-40			

NOTE.—Some blood drawn from the femoral artery just previous to death was found exceedingly black and venous in character, but rapidly changed to a bright arterial hue after a few moments’ exposure to the air.

Experiment IV.—Moderate-sized dog.

TIME.	DOSE.	PULSE.	PRESSURE.	TEMP.	REMARKS.
		150	115-125	103½°	Breathing regular. Pressure sometimes falling to 100, and during strong respiratory effort rises to 145.
0	gr. 1-20				Injected subcutaneously.
7				102½°	Respiration begins to be affected.
17		60	50-75	102¼°	Individual beat 25 cent. Respirations deep; nine to the minute.
27					
28		42	48-65	101¾°	Efforts at vomiting.
30			25-40	100¾°	Dog has just vomited.
30¼			105-135		
30¾			125-150		Vomiting ceased.
30½			130-160		Respiration almost ceased. Pressure has been lower.
31			90-115		Respirations irregular; four to the minute.
32½	gr. 1-20				Clot. The tube inserted in vessel on opposite side.
34		36	60-95	100¼°	
38½					
43			50-60	99¾°	There is violent purging. Stools liquid and greenish. Arterial blood very black, and clots easily.
53		50	35-75	98½°	Breathing very slow. Pulse irregular. During respiratory effort pulse and pressure both rise, falling again in the respiratory interval.
58					
62				97°	Blood very dark. Injection has had little apparent effect.
63		gr. 3-20			In peritoneal cavity.

TIME.	DOSE.	PULSE.	PRESSURE.	TEMP.	REMARKS.
88 m.	gr. 3-20				No marked effect.
89 "					In peritoneal cavity.
91 "					Violent vomiting of greenish fluid. Breathing very rapid and irregular.
91½ "					Respirations slow and labored; dog struggling violently for breath. Blood drawn from femoral artery very black, but becomes bright red after exposure to air.
96 "					Dog dead. Heart large and flabby, but filled with dark blood. Alimentary canal much inflamed throughout.

Experiment V.—A very stout, large terrier.

TIME.	DOSE.	PULSE.	PRESSURE.	REMARKS.
0	gr. 1-40	120	110-120	All or nearly all of this dose was lost in attempting to inject into the femoral vein.
5 m.		120	115-122	
9 "		144	117-123	
11½ "	gr. 1-40		115-123	Injected into femoral vein. Respiration exceedingly affected; very labored. Vomiting freely. Respiration almost arrested. Arterial blood perfectly black. Deep respiration; paroxysms at very long intervals.
13 "			120-125	
16 "				
17½ "			10-15	Decided change in color of blood. Respiration becoming more frequent.
18½ "			85-110	
19½ "			95-120	
20 "			135	Respiration in paroxysms at long intervals. During intervals pressure falls to 60-70, but rises to 60-100 after inspiratory efforts.
21 "			180	
22 "			245	
23 "		18	160	Cut one pneumogastric.
25¼ "			90-100	
26 "		54	70-90	
27 "			65-97	Respiration very weak. Cut remaining pneumogastric.
30½ "			68-80	
32 "			130	
32½ "			95-105	Into femoral vein.
34 "			90-100	
34½ "			80-87	
35 "			95-100	Respiration very labored. Injected into femoral vein.
35½ "			115-122	
36 "			110-115	
37½ "			68-73	Efforts at vomiting. Pulse very rapid. Arterial blood very black.
52 "	gr. 1-40		40-43	
52½ "			35-40	
53¼ "			40-45	Vomiting of a large quantity of mucus of deep greenish tint —probably due to bile.
54 "	gr. 1-40		65-70	
54½ "			75-80	
55 "			90-95	
59 "			95-100	
63 "				

A careful study of these experiments will show their complete agreement with those of my previous study. In Experiment III., the blood-pressure, after the first injection into the vein, fell to zero in the course of thirty seconds, and in one and a quarter minutes had risen again to 165,—the original point having been 110; and similar phenomena were also witnessed after subsequent injections. In Experiment IV., the alkaloid was thrown not into a vein, but into the cellular tissue, and the succession of phenomena was therefore less rapid, and, accordingly, in closer accord with what occurred in the trials with Bullock's preparation. Seventeen minutes after the

injection the pressure was about one-half what it was originally, whilst thirteen minutes later it was more than one-fifth greater than normal,—a fall of one-half, a rise of one-fifth.

In Experiment V., the alkaloid was thrown directly into the circulation, and in one and a half minutes the pressure, which had been 120, was down to 10, but in three minutes had risen to 245. It is very plain that the fall and rise not only take place much more quickly when the drug is thrown directly into the veins, but are also much exaggerated. This fact would seem to indicate that the primary fall is due to a direct action of the alkaloid upon the heart or its nerve-supply, whilst the secondary rise has its source in some indirect action of the poison. A reference to the record of Experiment III. or of Experiment V. will show that the alkaloid produces an intense disturbance of the respiration, and that the secondary rise of the arterial pressure was simultaneous with, and proportionate to, this disturbance. In my previous article the great probability that the rise was simply due to the excess of carbonic acid in the blood was fully shown, and the remarks thereon have already been quoted. In order to test absolutely the matter, the alkaloid was administered, and forcible artificial respiration was kept up. Under these circumstances, as will be seen from the following records, the secondary rise of the mercury in the manometer was altogether prevented, the arterial pressure being steadily depressed. If the bellows were kept quiet for an instant, however, and the animal left to its own unaided powers, the blood commenced to grow dark, and the pressure to rise, only to fall at once when the artificial respiration was again resorted to. In experiments hereafter detailed, these results were repeatedly confirmed; and, although at times other results seemed to be achieved, it was always found that a leak in the bellows or some other accident or circumstance had interfered with the efficiency of the artificial respiration. The experiments are as follows:

Experiment VI.—A stout dog of medium size.

TIME.	DOSE.	PULSE.	PRESSURE.	REMARKS.
0	gr. 1-40		100-110	Grain one-sixth of woorari injected into femoral vein, and artificial respiration practised. Into femoral vein.
1-10 m.			15 80	
½ "		102		
2¼ "			100-110	Slight vomiting, efforts interfering somewhat with artificial respiration.
3 "			80-100	
8 "			30-45	
14 "		52		Individual beat 13 cent. Arterial blood bright scarlet.
17 "		60	30-45	

Experiment VII.—A stout young pup.

TIME.	DOSE.	PULSE.	PRESSURE.	REMARKS.
0 m.	gr. 1-40	130	90-100	Into femoral vein. Artificial respiration. Pressure was falling rapidly, when the blood clotted in the tube.
1-10 "				

TIME.	DOSE.	PULSE.	PRESSURE.	REMARKS.
3	m.		80-85	
6	"		75-80	
15	"		45-50	
16	"		50	
23	"		40-45	

Experiment VIII.—A moderate-sized dog.

TIME.	DOSE.	PULSE.	PRESSURE.	REMARKS.
		90	115-125	Artificial respiration applied very actively.
0	m. gr. 1-50		130-135	Injected into the femoral vein.
½	"		65-75	
1	"	44	60-75	
2	"		80-95	
4	"	60	80-105	
5	"		90-110	
6	"	60	95-110	
8	"	93	90-110	
10	"	90	85-95	
11½	gr. 1-40			Into femoral vein.
11¾	"			After injection, pressure fell at once to 70, but a clot prevented further observation of the fall.
18	"		50-58	
19	"	88	50-58	

As a contrast to these experiments, and as showing the influence an excess of carbonic acid in the blood has over the depression of the arterial pressure caused by veratroidia, the following experiment is recorded. Although thus reported separately, for obvious reasons, it was in truth a continuation of Experiment VII.

Experiment IX.—A stout young pup.

TIME.	DOSE.	PRESSURE.	REMARKS.
0	m. gr. 1-40		Into femoral vein.
23	"	40-45	Cut pneumogastrics.
52	gr. 1-40	50-60	Into femoral vein. Artificial respiration suspended.
55	"	135	
56	"	145-170	
56½	"	210	Dog making violent respiratory efforts.
61	"	130-135	Blood black. Artificial respiration resumed.
61¼	"	55-60	

(To be continued.)

A CASE OF CARIES (?) OF THE VERTEBRÆ COINCIDENT WITH CANCER OF THE VISCERA.

BY H. C. HAND, M.D.

J. B., a native of Sweden, single, temperate, and a laborer, was attacked in the autumn of 1873 with pain in the region of the left hip. The pain increased in severity, and when he was first seen (Feb. 2, 1874) it was accompanied by considerable difficulty in locomotion. There was some tenderness on pressure in the groin, and about the same when pressure was applied over the sciatic nerve on the level of the great trochanter. No pain was excited by motion of the hip-joint, nor by driving the head of the femur against the acetabulum by sharp blows on the knee or heel. Soon he began to refer the pain to his knee, especially at one point over the inner condyle, and with this he suffered

almost as much as with the pain nearer the trunk. The left leg and thigh became daily more and more flexed, until at the time of his death the heel almost rested against the nates. During the last month of his life the right hip and thigh also became painful and flexed, but in a less degree than the left. He rarely complained of pain in his back, except when he lay in an uncomfortable position or when he was moved. On pressure there was some tenderness over the lower dorsal and the lumbar vertebræ, but this tenderness was not greater in degree than that found on each side of the spine over the lumbar muscles, and upon the ribs as high as the angle of the scapula. There was no projection of any of the spinous processes. He coughed a little, and occasionally raised some clots of blood.

About the 1st of February he noticed a small tumor under and in contact with the malar bone. This steadily increased in size until the time of his death, when it was as large as a walnut. It never gave him much pain. His appetite was always very poor; bowels constipated. He lost flesh and strength day by day, his skin became shrunken and inelastic, his complexion sallow and cachectic, and he died June 5, 1874. It should be observed that there was no bronzing nor other dark discoloration of the skin; its color was typically that which ordinarily accompanies the cancerous cachexia.

An *autopsy* was made thirty-six hours after death, by Dr. C. E. Smith and myself. The body was much emaciated. Both legs were extended and equal in length. As he lay on his back, the pelvis was inclined to the left side; it was easily straightened or even inclined to the other side, but resumed its original position by a hinge-like movement in the spine as soon as left free. On opening the cavity of the abdomen, the first thing attracting attention was the prominence of the lumbar vertebræ; in fact, this prominence was easily recognized during life through the thin abdominal wall. The point at which so free motion existed between the upper and lower halves of the body was at the second lumbar vertebra. The bony structure of the body of this bone had almost entirely disappeared, leaving some spiculæ only, the remainder of the space for the body being occupied, but not extended, by a bloody puruloid liquid. The bodies of all the other lumbar vertebræ were softened to such an extent that a scalpel could be readily thrust into them, causing the escape of a few drops of the bloody puruloid liquid mentioned above. The lower dorsal vertebræ partook of the same changes in a less degree. The lower lumbar vertebræ were very prominent, as before noted; so much so that the sacrum receded from them at almost a right angle. The breadth of the bodies of these vertebræ also seemed increased, being at least three inches, and probably more.

Some of the mesenteric glands were enlarged, but not greatly, and in two or three a few drops of pus had formed.

The kidneys were flabby and somewhat enlarged. Dispersed throughout their substance were numerous nodules, varying in size from a pea to a hazel-nut. These were round, well defined, more resisting than

the surrounding tissue, and on section showed a whitish and uniform structure.

The supra-renal capsules were each large and firm. The left weighed one ounce, the right two ounces. The whole interior of these organs seemed to have been replaced by a new formation of about the same consistence as the nodules in the kidneys. The color of this formation was grayish-white, its gross appearance slightly granular.

The liver was congested and dark. Round nodules, from the size of a white mustard-seed to a pea, were scattered throughout its tissue.

The spleen was double its average size. Its interior was like currant-jelly. No adventitious deposits were found in it.

The right pleural cavity contained about one quart of serum, by which, and adhesions at upper part, the lung was much compressed. No miliary tubercles and no cavities were found in it, but several nodules resembling in size, shape, color, and consistence those in the kidneys. One the size of a pea was found in the upper lobe of left lung; otherwise this lung appeared natural.

In attempting the removal of the tumor of the cheek, it was found to have involved the outer and anterior wall of the antrum. That part not blended with the bone was removed. Its size was about one inch by three-fourths of an inch in diameter. It was exceedingly hard and dense, and gave a creaking sound when cut. Its section was white, and exuded a little milky juice.

The microscopical characters of this cheek-tumor were—a fibrous stroma, cells of various shapes and sizes, the smaller ones containing one large nucleus, the larger ones several large nuclei; many of the smaller cells being elongated and spindle-shaped, more caudate; and finally, abundant free nuclei. Except the fibrous stroma, the new formation in the supra-renal capsules presented the same characters. The nodules in the kidneys had undergone degeneration to such an extent that the only microscopical appearances were multitudes of free granules and large many-shaped cells *filled* with granules. The same was also true of the nodules in the lung.

The above-named microscopical appearances were observed both by Dr. C. H. Boardman and myself, and, taken in connection with the general characters of the tumors, leave no doubt as to their cancerous nature.

The question of chief interest is that regarding the nature of the vertebral disease, whether it was a simple caries or a cancerous degeneration. Nothing but the comparative rarity of cancer, I think, would make us incline towards caries, and I believe that in regarding it as cancer we shall approach most nearly the truth.

The authors whom I have consulted in investigating the subject are either silent or eminently unsatisfactory. This little paragraph in Rindfleisch's "Pathological Histology" comes perhaps as near to the point as any: "A third, more rare, but so much the more characteristic form, is the diffuse carcinosis of the pelvic and adjacent vertebral bones, which presents itself clinically as an osteomalacia."

ST. PAUL, MINN., June 20, 1874.

TREATMENT OF CYSTIC GOITRE BY EVACUATION AND INJECTION OF THE SOLUTION OF THE PERCHLORIDE OF IRON.

BY J. EWING MEARS, M.D.,

Surgeon to the St. Mary's Hospital.

IN the London *Lancet* of May 11, 1872, Dr. Moirell Mackenzie reported a number of cases of cystic bronchocele which he had treated with eminent success by tapping and injecting with the solution of the perchloride of iron. As stated in the article, the cysts, by this method of treatment, were converted into chronic abscesses, and it was only necessary to conduct these to a termination in order to effect the cure of the bronchocele. The operation is exceedingly simple, and is described as follows. The cyst is first emptied, the trocar being introduced at its most dependent point, through the canula, which is allowed to remain; a drachm or more (the quantity being determined by the size of the cyst) of the solution of the perchloride of iron is injected, and the opening of the canula closed by a piece of cork or wood, cut to the proper size. The solution of iron is permitted to remain in the cyst for three or four days, according to the degree of inflammation which it is thought necessary to produce. At the end of the prescribed time it is withdrawn, the canula, with the opening closed, being retained in position. Poultices of linseed meal are now applied over the cyst, and when suppuration is fully established the plug in the canula is removed, and free drainage is secured. The canula is not removed until the discharge is limited in amount and its consistence such as to permit its easy exit through the wound. The duration of treatment was reported to vary from three weeks to four months.

Having under my care, at the time of reading this article, a patient who was suffering from bronchocele, I determined to treat it according to the plan so successfully employed by Dr. Mackenzie. Although I was not able, as will be seen, to follow to the letter the instructions given, still the success was complete, and I feel it a duty to report the case which so entirely confirms the plan of Dr. Mackenzie. It gives to the surgeon a method of treatment in these cases, which is at once simple and devoid of danger.

The patient, a female, aged twenty-eight years, first noticed the tumor in the neck some twelve years ago. Its growth had been very slow, and for a period of four years it seemed to remain stationary. During the last year it had enlarged in size until it produced quite a deformity, and at times interfered with swallowing. It was, at the time of operation, the size of a large-sized hen's-egg, being developed rather more to the left of the median line of the neck. It was freely movable, rising and falling with the movements of the larynx and trachea in deglutition. Various plans of treatment had been employed to effect its removal. I had already tried simple tapping and the internal administration of sorbefacient remedies, with also local applications.

Owing to the failure to obtain the proper form of trocar and canula, I was unable to secure the latter in the cyst after I had tapped it, and injected a drachm of the solution of the perchloride of iron. The injection was, however, entirely retained by the closure of the puncture made by the small trocar. On the third day symptoms of inflammation appeared, and the neck was quite swollen; slight febrile movement was also present. On the fourth day I reopened the cyst, from which there escaped a small quantity of a viscid, tarry substance. Poul-tices were now applied, and in a few days suppuration was established, the pus escaping through the puncture, which was kept open by the use of the probe. In six weeks the discharge ceased and the opening closed, leaving but a slight swelling over the site of the tumor. Three months after, when I saw the patient, this swelling had disappeared, and a small cicatrix marked the position of the cyst.

Dr. Mackenzie has reported to the Clinical Society of London the results of this plan of treatment in sixty-eight cases of cystic goitre and nineteen of the fibro-cystic variety. Of the cystic form fifty-four were cured, eleven did not require treatment, and three were in subjects on whom, by reason of cardiac disease, it was thought undesirable to operate. The results in the fibro-cystic varieties were equally favorable. The advantages of this plan of treatment are set forth in several clearly-stated conclusions, at which Dr. M. had arrived from a study of his cases. The hæmostatic property of the iron is alluded to as of value in these cases. The frequent occurrence of sloughing after the injection of iodine renders this remedy dangerous, and it should therefore not be employed.

TRANSLATIONS.

DOES CHLORAL INTRODUCED INTO THE SYSTEM PRODUCE PHYSIOLOGICAL EFFECTS SIMILAR TO THOSE OF CHLOROFORM?—The *Gazette Méd. de Paris*, July 11, contains a discussion of this question by the editor apropos to certain proceedings in the Académie de Médecine. In the Academy, M. Colin, who had been advocating the use of intravenous injections of chloral, was asked whether this substance is or is not converted into chloroform in the blood, and, if the former is the case, what advantage can possibly accrue from the administration of chloroform by this means over inhalation as usually employed. To this question no reply was given, seeming to indicate that the action of the two substances in the economy was assumed by the Academicians present to be identical.

To this view Dr. Laborde, the writer of the article in the *Gazette*, takes vigorous exception. It is difficult, he thinks, to understand how any physiologist who has experimented with chloral can admit that this substance comports itself in the organism like chloroform. The phenomena which constitute the essential features of this difference are as follows. The period of excitement which is habitual in chloroform-inhalation does not exist after the administration of chloral. Experiment shows that this difference is not due to the method of administration, since chloroform injected into the

veins or introduced into the stomach or rectum is followed by the same excitation as that which occurs subsequently to inhalation.

Chloral, as is known, produces sleep rapidly, while the anæsthesia which follows the sleep is not well marked or persistent until a further and sufficient dose has been administered. Once obtained, the anæsthesia, like the slumber, is quite prolonged, and both continue for an equal period. The persistence of sleep and anæsthesia may be more or less long, but they are always longer than the same effects when produced by chloroform.

On the other hand, with chloroform the anæsthetic effect dominates the properly hypnotic effect, and the first may be established and persist without the second having been produced. Every surgeon knows that there are certain patients in whom slumber can be produced by means of chloroform only with difficulty, while a sufficiently anæsthetic effect may be brought about without much trouble.

The sleep produced by chloroform is usually uneasy, disturbed, and full of dreams, while that brought about by chloral is calm and peaceful.

What is most characteristic, however, in the differences between the respective actions of chloral and chloroform is, on the one hand, the mode of awakening, and on the other the consecutive phenomena. The animal or man who has been under the effect of chloral awakes as if from a natural slumber. It is hardly necessary to say that this is far from being the case in slumber or anæsthesia produced by chloroform.

Although a certain proportion of chloral introduced into the blood may be converted into chloroform, yet the fact that in injections, etc., of chloral, the breath, the blood, etc., smell of chloral and not of chloroform, shows that much of this substance remains unchanged. M. Laborde does not believe in the intravenous injection of chloral, which, if introduced in concentrated doses, leads, he thinks, to local trouble, and if introduced in diluted solutions, exposes the patient to greater danger from the necessarily repeated operations.

RENAL CONGESTION AND APOPLEXY; THEIR RELATIONS WITH CEREBRAL HEMORRHAGE.—Dr. Aug. Ollivier, in the *Archives Générales* for February, 1874, communicates a series of observations on this subject, including, 1, hospital cases; 2, physiological experiments. Under the first head Dr. O. gives careful notes of four cases of cerebral apoplexy, with autopsies. Under the second division he details a series of experiments practised upon rabbits, including irritations and incisions in the floor of the fourth ventricle, various parts of the hemispheres, the origin of the right acoustic nerve, etc.

The object of these experiments was to reproduce, as far as possible, the conditions found in hemorrhage into various parts of the brain. The results of the physiological research coincided with the clinical observations, and Dr. O. remarks that according to these facts albuminuria may be observed not only in hemorrhage of the pons, but also in hemorrhage into other parts of the encephalon. Dr. Ollivier concludes that albuminuria of cerebral origin is more frequent than up to this time has been supposed. In the present state of science it is impossible to fix with precision from the existence of this symptom the seat of a hemorrhagic clot, while in a case where the signs of a lesion of the pons are wanting in an apoplectic, one may say that the presence of albumen in the urine indicates either a clot at the base of the encephalon or an extensive hemorrhage compromising this base. In either case it constitutes a prognostic sign of great gravity.

A. V. H.

PROGRESSIVE PERNICIOUS ANÆMIA.—Under this title Prof. H. Immermann describes (*Deutsches Archiv für Klin. Med.*, 13ten Bd. 3tes Heft, 1874) three cases of a peculiar affection first alluded to by Biermer in 1872. Prof. I.'s cases are given at length and with most careful details. From the remarks he makes on the affection we extract the following conclusions:

1. There is a peculiar form of a high grade of anæmia which is distinguished by a progressively pernicious course, and appears almost invariably to terminate fatally.

2. This affection is to be distinguished from chlorosis, leucæmia, and other pathological processes as a peculiar form of disease, to denote which the name given by Biermer appears most convenient.

3. The etiology of this disease is obscure, since although we know certain aiding and abetting causes, we do not understand the essential (perhaps specific?) one; the geographical distribution of the affection displays interesting variations.

4. The peculiar symptoms of the disease during life, as well as the anatomical changes observed subsequently, indicate it generally as the result of blood-alterations, which the essential and primary disturbance in this affection establishes. The pathogenesis, however, of this excessive anæmia is not clear, since it may be due either to a diminished formation of the constituents of the blood or their rapid destruction, one or the other of which would lead to a similar result.

THERAPEUTIC NOTES.

CURE OF IN-GROWING TOE-NAIL.—Dr. Ozanam (*L'Abeille Méd.*, July 6) regards the surgical operation at present commonly resorted to for the relief of this affection as needlessly cruel. The tearing out of the nail, or portions of it, leaves the toe in a tender condition for a long time, sometimes permanently. The plan which Dr. O. suggests as a substitute is as follows. A nick is made in the centre of the edge of the nail, extending in to its attachment. Then the upper surface of the nail is scraped along the middle line until it is thinned nearly down to the quick. A small piece of sheet-rubber is afterwards inserted on either side of the nail with the aid of a spatula, so as to form a sort of gutter around the edge, and to separate it from the adjoining flesh.

Dr. O. lays great stress upon this part of the treatment, and in particular upon the employment of rubber. Lead, he remarks, is too hard, charpie too soft and yielding, while the elasticity of the rubber on the one hand and its comparative softness on the other serve to keep up a constant but gentle pressure on the inflamed tissues without giving undue pain. Thus, with the elastic pressing up the outer edges of the nail and the thinness of its centre allowing a certain amount of yielding, it gradually becomes flatter, and its edges cease pressing upon the adjoining flesh. Should fungous granulations exist about the in-growing edges of the nail, it will be proper to apply some alterant, and the best for this purpose is powdered nitrate of lead, which reduces the fungosities and rapidly arrests suppuration. After the condition of the nail is once remedied, it is necessary to keep the central portion scraped thin for some months, until it becomes flatter and assumes a more normal form.

MERCURIAL INUNCTIONS IN SYPHILIS.—M. Panas (*Jour. de Méd. et Chirurgie prat.*) remarks that the sole objection to the use of mercury in this manner is the exposure to stomatitis and local irritative eruptions of the skin. To prevent the former, M. Panas recom-

mends the use of astringent dentifrice powders from the beginning of the treatment, with watchful care of the teeth. One or two vapor-baths should also be administered to the patient daily. The use of tobacco should be discontinued as far as possible. It is principally in the graver forms of the disease that this treatment is found applicable,—when the nervous system and bones have been attacked. In these cases the most unhopd-for success is occasionally obtained. In new-born syphilitic children mercurial frictions should be used exclusively. M. Panas makes use of the ordinary mercurial ointment, to the amount of one to two drachms daily. The frictions are made in the evening before retiring, and should be continued for five minutes or so, over a limited portion of the body. They may be kept up for a month or six weeks, and may be recommenced if any new signs of the disease should appear.

TANNATE OF QUININE IN CHRONIC ALBUMINURIA.—Bouchardat (*L'Abeille Méd.*, July 6) says, "I am in the habit of employing the sulphate of quinine in chronic albuminuria according to the method of Dr. Devouves, and occasionally with unhopd-for success. The dose I employ is eight grains, in a cup of strong coffee, three times a day. This is continued for six days, and at the end of that time scammony or some similar purgative is administered. After one or two days of rest the patient is again placed on the use of quinine; and I have frequently continued this treatment for more than a year. The food of course should, during this treatment, be highly nutritious. Lately I have been substituting the tannate of quinine for the sulphate, in doses of ten to twenty grains, three times in twenty-four hours, given in a similar manner. The digestive apparatus supports the tannate better than the sulphate."

INJECTION OF CHLORAL INTO THE TRACHEA.—At a recent meeting of the Société de Biologie, M. de Bellesme suggested the introduction of chloral into the system by this means in cases where the circulatory and absorbent functions are almost in abeyance, and where therefore subcutaneous or intravenous injections cannot be practised with reasonable hope of success. The process simply consists in inserting the needle of a hypodermic syringe into the trachea, at a point about one finger's-breadth below the cricoid cartilage, and slowly injecting the solution, which can be used in much larger quantities than by the subcutaneous method. This method is likely to prove serviceable in tetanus, hydrophobia, and the algid stage of cholera.—*Le Progrès Médical*, May 23.

BLENNORRHAGIC EPIDIDYMITIS.—M. Richert never uses leeches to the root of the penis, and rejects absolutely collodion strips for the scrotum, which cannot be removed without giving great pain to the patient. He also rarely has recourse to puncture of the tunica vaginalis. Repose in bed, position of the scrotum, which should be well kept up by means of a rubber or linen support, and the application of resolvent compresses, lead-water, or even cold water alone, serve to effect a cure.

ANTISPASMODIC PILLS.—

R Pulv. assafetidæ,
Pulv. camphoræ, aa ʒvj;
Ext. belladonnæ, ʒii;
Pulv. opii, ʒi;
Syrupi, q. s.—M.

Ft. in pil. No. clxxx.

One to be taken the first day, two the second, and so on until six are taken daily, or two three times a day. Useful in hysterical and spasmodic nervous affections, in connection with bromide of potassium in doses of ten to fifteen grains.

PHILADELPHIA MEDICAL TIMES.

A WEEKLY JOURNAL OF

MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY

J. B. LIPPINCOTT & CO.,

715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, AUGUST 22, 1874.

EDITORIAL.

AN INTERNATIONAL CODEX.

A REVIEWER of the United States Pharmacopœia, in the *British and Foreign Medico-Chirurgical Review* for January, 1874, made a proposition which has not, according to our thinking, attracted the notice which it deserves. Indeed, the only response which it has elicited is an article from the pen of Dr. Charles H. Thomas, published in the *American Journal of Pharmacy*, and commented upon by the editor of that journal. The proposition made by our British confrère is that instead of England and the United States having each their own peculiar Pharmacopœia, an international one shall be prepared and be received as the sole standard authority in both countries. The advantages to be derived from this fusion are very obvious. Any measure which tends to unite the two countries more closely together is indeed just so far advantageous to both; but, leaving out of sight such generalities, it is evident that much specific good would accrue from the proposed change. The literature of the two countries is to-day almost a common one, and is continually interfusing more and more completely; the intercourse by travel for pleasure and business is incessant and profuse; commercial relations are daily increasing in strength and number. Without occupying more space with details, these considerations or hints are sufficient to show the importance of the proposed unification, and it is only necessary to say a few words in regard to the present disunity.

This is the more imperative since no less an authority than Prof. Maisch has expressed an opinion so worded as to give the impression that the two Pharmacopœias are practically identical. The mere fact that the fundamental weights and measures are different in the two Pharmacopœias, the United States codex using apothecaries' weight and wine measure, the British standard employing avoirdupois weight and imperial measure, is sufficient to prove the diversity of the two. Taking, however, Prof. Maisch's own tables, we find that the tincture of aconite root is more than, and the tinctures of hyoscyamus, of nux vomica, and of cantharides are nearly, three times as strong in the United States as in the British Pharmacopœia. Surely, without occupying more space, these few data are sufficient to show the differences between the two standards; any points of agreement only render the assimilation of the two Pharmacopœias more easy.

The chief intrinsic obstacle to the unifying of the two standards is the diverse systems of weights and measures. This difficulty is readily met by banishing weights and measures altogether from the Pharmacopœia, and using in the formulæ "parts by weight." Indeed, at the late convention for the revision of the United States Pharmacopœia, the acting committee were directed so to prepare the formulæ in the edition of our national standard just published; but the autocratic gentlemen who were intrusted with the behests of the convention have deemed fit to disregard entirely the wishes and directions of those who appointed them; so that the Pharmacopœia appears in the old lumbering style.

The chief practical difficulty in effecting the desired unification is to be found in getting the machinery at work. Fortunately, at the late convention the revising committee was made perpetual, so that it can at any time be got together if an emergency should arise. This committee is, however, so conservative in its composition that no originating movement is to be expected from it: indeed, if it should heartily respond to a summons, it would do more than seems at present probable. The surest and most practicable method of bringing about the desired change would be for the English authorities to make advances to this committee, which undoubtedly has the right to make whatever alterations in our standard it chooses, and could, if it would, enter actively upon the work of unification.

It is, however, not very probable that the Old World will see fit to come to the New: the natural but false pride of seniority is against it, so that

some other way of getting at the matter must be devised. The only plan which appears plausible is for the American Medical Association at their next meeting to appoint, with power to act, a committee, which shall attend the following meeting of the British Medical Association and ask for the selection of a committee of conference, the two committees to form a joint commission to arrange the details for the actual performance of the work. This plan seems to us perfectly practicable, provided that sufficient enthusiasm can be awakened and sufficient judgment be exercised to get the right men to agree to serve and to be appointed upon the first committees.

Some provision should also be made by which this committee should be completely *en rapport* with the existing committee upon the revision of our standard, and with the pharmacutists of the country as represented in their national association.

CORRESPONDENCE.

MASSAGE EXTRAORDINARY! A CANINE SURGEON.

TO THE EDITOR OF THE PHILADELPHIA MEDICAL TIMES:

"A MOST remarkable instance of sagacity and animal reasoning took place yesterday afternoon at the residence of Whitfield Crawford, southeast corner of Seventh and Madison Streets, in this city. The principal actors in the case were a large dog belonging to Mr. Crawford, of the St. Bernard and Newfoundland breed, about two years old, who readily answers to the name of Carlo, and an ordinary domestic house-cat named 'Dick.' Between the two a strong feeling of friendship has always existed, each sharing the other's meals, and at night Dick, appreciating a soft bed, always found it by lying upon the top of his good-natured friend Carlo.

"On Wednesday last, on Mr. Crawford's return from market, he cut a piece of fresh meat into small pieces for Dick, but accidentally a needle and thread lying close by got mixed up with the meat. This poor Dick swallowed, or attempted to swallow, with the meat, but, not succeeding, the needle stuck in his throat, from which cause he of course suffered intensely, and in his sufferings he had the entire sympathies of his friend Carlo. Like a skilful physician, Carlo set about discovering the seat of the disease, which he found existed in Dick's neck.

"After an apparent consultation between the two, one as patient, the other as doctor, Carlo commenced operations by licking Dick's neck, the cat holding its head to one side to give Carlo a fair chance. The licking operation continued all day on Thursday, and at intervals through the night, Carlo occasionally pausing to press his tongue against the neck of his feline friend, as if trying to force some sharp-pointed instrument on the inside through the cat's neck to the outside. Yesterday, the same operation was continued by Carlo, until about four o'clock, when he was seen, with his whole body quivering with excitement, trying to catch something with his teeth, in which he succeeded, and giving a sudden jerk he pulled the needle through the hide of the cat, where it hung by the thread which still

held it from the inside. The remainder of the operation was performed by a daughter of Mr. Crawford, who pulled the thread through and stuck the needle in the fence close by. The joy of Carlo knew no bounds, and, frisking his bushy tail about, and rubbing his shaggy sides against his master, he showed his full knowledge of what he had done by going to the cat and licking the wound in the neck, and then to the needle in the fence, which he examined very minutely, saying, in actions almost as plain as words, 'See what I did.' A son of Mr. Crawford coming home from his labor was met by Carlo, who turned and ran to where the needle was, and smelled it as if to explain the case more fully to the new-comer."

"Go to the ant, thou sluggard!" says the wise man, to inculcate a lesson of diligence. "Go to the dog, thou stupid!" we may say to the surgeon, who on a similar emergency to the one recorded above would undoubtedly have attempted to remove the foreign body by its avenue of entrance. Apart from the wonderful interest of the story as witnessing to the animal's sagacity or reasoning powers, it is a remarkable tribute to the surgical possibilities of manipulation,* pure and simple,—a veritable triumph for the movement-cure. It also indicates a mode of procedure for the extraction of a needle from the œsophagus which is entirely free from the danger of laceration so often produced by our blind and bungling and more violent efforts. I will simply add that I have taken pains to verify the relation, and have had the extreme pleasure of taking "Carlo's" paw and giving him the salutation of a confrère.

He is a huge specimen even of those large species, while the kitten is but half grown. The wound is directly in the median line, and at a point which in the human being would be about opposite the root of the tongue. As there is no evidence of escape of air from it, I conclude that it passed immediately over the epiglottis. It is a round hole, the twelfth of an inch in diameter, suppurating, but with very little inflammatory action around it. The skin is denuded of hair for about half an inch around. The kitten is evidently "a sick child." This is the third day since the operation, and the first day that it has been able to eat. It, however, "takes more notice," and I think a favorable prognosis may be ventured on.

Dr. "Carlo" appeared to agree with me in this view of the case. The extract is from the *Wilmington Commercial* of this evening.

BENJAMIN LEE.

1503 SPRUCE STREET, PHILADELPHIA, August 1, 1874.

ETHER AS AN ANTHELMINTIC.—Prof. Vogel announces a new application of this anæsthetic, namely, the destruction of tape-worms. The ether is enclosed in a gelatin capsule and swallowed. It soon becomes vaporized in the stomach, (?) and the worm, then becoming stupefied, is easily removed by any of the usual remedies, against which, when awake, it offers strong resistance!—*Journal of Applied Chemistry*, August, 1874.

* Carlo's tongue was simply his substitute for a hand.

PROCEEDINGS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

THURSDAY EVENING, JUNE 25, 1874.

THE PRESIDENT, DR. WM. PEPPER, in the chair.

DR. DE F. WILLARD presented the specimens from a case of *tubercular phthisis, with cavities, ulceration of intestines, and cystic kidneys*, from Mrs. A. B., æt. 68, admitted to the Presbyterian Hospital with a history of long-standing cough and diarrhœa. She was supposed, some years since, to have an ulcer of the stomach, but nothing further is known in regard to her history. On admission she had abundant expectoration and frequent, profuse, and offensive stools, and sank rapidly.

Autopsy, twelve hours after death.—Body in ice; amount of rigor mortis consequently uncertain.

Body emaciated.

Right lung.—Small cavity at apex. Lung filled throughout entire extent with patches of miliary tubercles. Softening taking place at several points.

Left lung.—Apex occupied by a large cavity, containing an ounce of purulent fluid. At numerous points in both upper and lower lobes small cavities were encountered, while scattered through all the substance of both these lobes were abundant tuberculous spots of the miliary variety. Both apices firmly adherent to parietal layer of pleura. Small excess of fluid in pleural cavity.

Stomach.—Near the pylorus was found an ulcer three-quarters of an inch in length by one-half of an inch in breadth, extending through the mucous membrane into the submucous tissue. The edges were steep, and the base occupied by a dark material resembling ecchymosed blood.

Intestines.—From the duodenum to the rectum there were from one hundred to one hundred and fifty ulcers, of size varying from that of a pin's head to an inch in diameter, and presenting various stages of ulceration and healing action. Some were apparently entirely healed, and in their cicatrization had so drawn upon the mucous membrane that it presented a peculiar appearance, with folds radiating from their centres in every direction, the membrane being puckered longitudinally, transversely, and obliquely.

These ulcers were most numerous in the lower portion of the ileum, the cæcum, and the ascending colon, but were quite abundant in every portion of both small and large intestines.

Liver.—No abscesses or other abnormal appearances.

Spleen.—Also normal.

Kidneys.—Right: hypertrophied, but normal relation preserved between the cortical and medullary portions. Left: densely indurated, and with the capsule so adherent to the surrounding fat that it was removed only with great difficulty.

The secretory substance was apparently entirely destroyed, and its place occupied by six or seven cysts, containing a thick, purulent fluid. One cyst, near the upper end, was filled with a peculiar, white, pasty, and nearly solid substance, which resembled plaster of Paris when prepared for making casts, but was unctuous and smooth. The nature of this has not yet been determined by the microscope, but will be at the first opportunity.

The PRESIDENT desired an expression from the members as to the state of the kidney.

Dr. JAMES TYSON remarked that he thought no opinion could be given with regard to changes in the structure of the chief portion of the kidney without microscopic examination. He was, however, quite familiar with cysts of the kind found in this kidney.

The white, pasty matter is undoubtedly fat in a state of extreme comminution, in other words, *emulsified*, as would doubtless appear on microscopic examination. Its source has been most probably similar to the same matter found in ovarian tumors,—a fatty degeneration of proliferating cells.

The PRESIDENT alluded to the possibility of this cyst becoming a centre of infection, and thus the origin of a tuberculosis. He called attention also to the co-existence of gastric ulcer and intestinal ulceration, alluding to the rarity of its occurrence.

Dr. R. M. BERTOLET said he thought it evident this was not a dilatation-cyst, so called, as shown not only by the difference in its contents, but also in the absence of hydronephrosis,—dilatation of the pelvis at the expense of the medullary and cortical layers,—and other conditions usually attending the presence of such cysts; that the mere naked-eye appearances of the cheesy-like contents of the cyst offered no reliable criterion as to their tubercular nature; that without a microscopic examination it was even doubtful whether we had to deal with the cheesy degenerated masses. While he admitted the occurrence of such cheesy foci in the kidneys, whose presence, as well as those foci found in the lungs and other organs and glands of the body, might give rise to the eruption of true miliary tubercles, yet he thought that in other situations they did not usually present so pearly-white a lustre as this specimen.

Further, true tuberculosis of the kidney is not a very rare condition: the tubercles being disseminated beneath the capsule and the mucous membrane lining the pelvis. Great care should, however, be exercised in the discriminating use of the terms "tubercle" and "cheesy masses."

The kidney was referred to the Committee on Morbid Growths.

Dr. F. P. HENRY presented the *diseased supra-renal capsules* from a case of *Addison's disease*.

"T. G., æt. 23, sailor, born in Trieste, Austria, was admitted to the Episcopal Hospital January 4, 1874. The diagnosis on admission was epilepsy, based upon the fact that he had previously had attacks of that disease. He came under my care on May 1, and at that time was suffering from obstinate constipation, with nausea and occasional attacks of bilious vomiting. His pulse was extremely feeble, and he complained of a constant sense of weakness. The man was naturally of a very dark complexion, but there was a peculiar dinginess in the color of his skin which attracted my attention from the first, and which, taken in connection with the other symptoms, led me to suspect that I had to deal with a case of Addison's disease. At times there was great tenderness about the umbilical region, and on one occasion, after palpating the abdomen, the patient uttered loud cries for ten or fifteen minutes, and seemed in great agony. Nothing was found after death to explain this symptom. The urine was examined at different times, and only once presented a faint trace of albumen. The lungs were examined and declared sound, as they proved to be at the post-mortem.

"The prostration became gradually more marked, the pulse more feeble, and the stomach so irritable that the greater portion of the food was vomited. There was frequent vomiting of bile. During the last three days of life there was suppression of urine; Dr. Reed, the resident physician, passed a catheter, but no urine flowed through it. He then received a vapor-bath.

"The man died on June 22. The *autopsy* was made six hours after death. The intestines, both small and large, were found to be quite empty and decidedly contracted. The liver, stomach, and pancreas presented no gross appearances of disease. Spleen slightly enlarged and congested; lungs healthy. The kidneys and supra-renal capsules were removed together. The

latter organs are seen to be much enlarged. In the fresh state, on section, they were of a yellow color, and the opposite surfaces of the section poured out a quantity of thick, yellow matter resembling pus. Small nodules were found in both organs which presented the gross appearances of softening cheesy masses. Under the microscope, a section of one of the diseased glands presented a large quantity of granular matter, a few large oval cells containing oil-globules, and a number of small, irregularly-shaped cells, judged to be tubercle-corporuscles. No trace of the normal structure of the gland, such as its division into cortical and medullary substance, was observed in the specimen examined.

"I omitted to mention that a moderate quantity of adipose tissue was found in the abdominal walls and in the mesentery and great omentum, and that the bladder was empty."

The specimens were referred to the Committee on Morbid Growths.

The PRESIDENT said there were several points of clinical interest about this case, not the least of which was its connection with epilepsy. Recent investigations tend to associate some forms of this latter affection with lesions of the cervical sympathetic; and so, in well-marked cases of Addison's disease, the nature of many of the symptoms, as well as the results of some post-mortem examinations, shows that the abdominal sympathetic nerve is involved.

As to the connection between the melasma and the lesion of the supra-renal capsules, although not so close as Addison thought, at the same time examination shows that cases in which lesions of these bodies are not found are generally wanting in certain essential symptoms of the disease.

He had seen cases where the autopsy proved both the existence and absence of the lesion of the supra-renal capsules; but whenever the typical symptoms were present, such as disturbance of the heart, disposition to syncope, irritation of the stomach, tendency to vomiting, gastric tenderness and associated nervous phenomena, there was always marked caseous degeneration of the supra-renal capsules. In the last of these cases, also, critical examination of the solar plexus indicated disease. There was an increased amount of fibroid tissue in the ganglia, atrophy of the nerve-tubules, and excessive pigmentation of the ganglionic cells. Whether this latter was pathological or not, he could not positively aver, since even in health the pigmentation of these cells is often marked; but it is sufficient that lesions of the solar plexus have been found to exist, in some cases, where it has been carefully examined.

The PRESIDENT presented a *portion of lung from a case of pulmonary phthisis, with cavities (bronchiectatic?), hæmoptysis, death from asphyxia. Enormous clot of blood in a large cavity in right lower lobe.*

"Mrs. C., æt. years, with disposition to phthisis inherited from her mother, enjoyed excellent health until early part of 1873. Cough then set in, at first slight and dry, but later attended with abundant nummular purulent sputa. There was but moderate hectic, no hæmoptysis, but quite rapid emaciation and great prostration. Menstruation continued regular. She was under the care of various physicians, and first consulted me in April, 1874. There were then the physical signs of several small cavities along the anterior surface of the right lung, and of a larger one at the angle of the right scapula. In the left lung there were several points of softening in the upper lobe. The lungs were evidently emphysematous. There was extreme prostration, with marked dyspnœa.

"The treatment consisted chiefly of quinia and iodide of iron. On June 17 there occurred a profuse hæmoptysis. This was soon checked, but was followed by

increased prostration and frightful dyspnœa, with greatly diminished cough and expectoration. The sputa became more and more free from blood, and for forty-eight hours before death were light chocolate-color. Respiratory sounds in the right lung were less clear, and associated with diffused moist and sonorous râles. Death occurred from asphyxia, on the 23d.

"At the post-mortem examination, there was marked emphysema of the lungs. In the left one there were several small cavities, varying in size from one-third to three-fourths of an inch, and deeply seated. These cavities communicated with bronchi, and were lined with smooth membrane. Elsewhere there were several nodules of caseous matter.

"On right side there were several small cavities in anterior part of lung, but the largest was on posterior surface, about level of angle of scapula. This vomica was fully three inches in diameter; it was very superficial, lying immediately beneath the somewhat thickened pleura, which was adherent to the costal pleura over this space. The cavity itself was limited by a distinct fibrous capsule, which could be dissected away from the surrounding lung-tissue as though it had been a heterogeneous cyst. Two bronchi of considerable size entered it. Its lining membrane was slightly roughened and granular; in places a faintly-marked trabecular appearance was visible. On lower wall of cavity there was a button-like prominence three-eighths of an inch in diameter and one-fourth of an inch high. Probably the hemorrhage had proceeded from this spot. The entire cavity was filled with a solid, dark clot of blood, weighing not less than half a pound. None of the other cavities contained blood. The bronchi were filled with thick muco-purulent matter. There were also scattered nodules of cheesy matter, some firm and partially fibroid, others disintegrating. These were usually circumscribed by a fibrous capsule. There was no diffused bronchiectasis. The heart was healthy. The abdominal organs were not examined."

Dr. JOHN H. PACKARD asked whether the small projections into the cavity were the source of the hemorrhage.

The PRESIDENT replied that he suspected this to be the case, but he did not know.

Dr. PACKARD referred to a specimen he had exhibited November 22, 1863, in which several similar cavities, or cysts as they were then called, were present. It was derived from a lady aged 52, who had been addicted to the immoderate use of ether. The cysts were of various sizes; the clinical history shed no light upon their origin or pathology.

Dr. J. EWING MEARS presented a small portion of an *epithelial tumor of the vagina*, which he had removed from a patient, and gave the following brief history of the case:

"She is aged 35 years, is a native of England, and has been married eight years. She has never been pregnant, and menstruation is in every respect normal.

"During the last fall and winter she was treated for ulceration of the womb, and was relieved. Her attention was first directed to the growth in the vagina by a hemorrhage which occurred in May last. Hemorrhages, more or less severe in character, have occurred from time to time, for the relief of which she has used styptic injections. Her general health has been good, and she has been able to perform her household duties without interruption.

"On making a digital examination, an irregular, soft mass could be distinctly felt occupying the posterior wall of the vagina. It was situated at a point corresponding to the junction of the upper with the middle third of the canal. The growth was sessile, the attachment measuring in its long diameter about an inch, and transversely about an inch and a half. Between the mass and the os uteri the wall of the vagina was

smooth and entirely free from any morbid growth. The os tinæ was normal, and free from disease.

"On introducing a Sims's speculum, the tumor could be easily examined, and presented to the eye the appearances described above.

"Slight hemorrhage followed the digital examination, and was readily checked.

"In removing the tumor, an attempt was made to accomplish this by means of the wire *écraseur*: owing to its soft, spongy character, this was not successful. A hooked periosteal elevator was then employed, with which and the finger-nail the entire mass was removed, leaving a smooth surface on a level with the vaginal wall. Hemorrhage was not copious. After thoroughly cleansing the vagina by injections of water, pledgets of lint saturated in Monsel's solution of iron were introduced, which effectually checked the hemorrhage; after the expiration of twenty-four hours these were removed, and the surface was found coated with scales formed by the styptic. In a few days these were removed, leaving a small healthy-looking raw surface.

"Remarks.—This case seems to possess one or two features which it may prove of interest to the Society to consider. At first, guided by the history of the case as presented, Dr. Mears was disposed to regard this growth as a papilloma of the vagina, and in view of this fact had prepared to encounter more difficulty from hemorrhage in effecting its removal. He was struck, therefore, by the comparatively slight amount of bleeding which occurred, and at once concluded that he had to deal with a pure epithelioma. Subsequent microscopic examination confirmed this conclusion, since there was an entire absence of the dendritic growths which characterize the papillary or villous form of cancer. Large quantities of variously-shaped nucleated cells, many containing granules and a delicate stroma, were all that could be seen in a number of portions which were examined.

"It has occurred to Dr. Mears that this possibly may be one of those instances in which there has been a transition of papilloma into epithelioma as noted by Rindfleisch. This belief is founded solely upon the statement as to the free hemorrhages which occurred in the early stages of the disease.

"The extremely rapid growth of the tumor is proven by the statement of the physician by whom the patient was treated for cervical endometritis, and who assures Dr. Mears that three months ago there was not a sign of any morbid growth in the vagina. Dr. Mears has, in studying this case, been interested in learning that, so far as the records of this Society furnish evidence, and also from the statements of several physicians and surgeons with extended experience in the treatment of the surgical diseases of the female generative organs, who have been interrogated, primary cancer of the vagina is not of very frequent occurrence. The volumes of Transactions of this Society published, now three in number, do not contain the report of a case. During the past two years two cases have been reported to the Society,—one by Dr. Parry, and one by Dr. Mears."

Dr. JOHN H. PACKARD read the history of a case of *tuberculous deposit at base of brain*, with obscure symptoms:

"A. Y., æt. two years, was first seen by me May 31. His parents had moved over from West Philadelphia about ten days before, and on his becoming indisposed they placed him under the care of a homœopath, who gave him something to check the diarrhœa, with dark and offensive stools, which was then his chief symptom. The child continuing to droop and to show an increasing tendency to drowsiness, they sent over for Dr. M. B. Musser, their former attendant, who advised them to send for me.

"During my attendance, the child's symptoms were

chiefly stupor, with occasional accessions of jerking, affecting more especially the right arm and leg. The mother said she noticed some strabismus, but could not, of course, tell which eye was most affected. The thumbs were not drawn in. The child took scarcely any food, but did not vomit. The bowels were inactive unless medicine was given. The pulse was from 90 to 93 in the minute, throughout, except on the last day, the sixth of my attendance, when it grew much more rapid and feeble, and the temperature seemed normal to the hand; there was occasionally a marked degree of dryness and harshness of the skin.

"A few days before death it became evident that vision was gone; the eyes were normal in appearance, but the pupils were unaffected by light.

"Death took place quietly on the 6th of June.

"Autopsy, made by Dr. G. S. Gerhard and myself, twenty hours after death. Head only examined. Body in ice, and stiff.

"Skull-cap normal in thickness and firmness; somewhat adherent to dura mater, which seemed normal. Some subarachnoid effusion.

"All the veins on the surface of the brain were distended with blood, those on the right side particularly so. A good deal of serum flowed out as the membranes were divided, perhaps partly from the ventricles.

"Sections of the brain showed less than normal vascularity. The central portions of the hemispheres, especially the left, were very soft. The corpus callosum was entirely diffuent, and the fornix, choroid plexuses, and septum lucidum were scarcely traceable. All the ventricles were dilated with serum, and some granular deposits existed along the plexuses.

"On the base of the brain there was a good deal of effused lymph; a large mass existing in the interpeduncular space, on the front of the pons Varolii, and along down the medulla oblongata and spinal cord.

"In the fissure of Sylvius on either side, around the middle cerebral artery, a granulated mass of tuberculous deposit existed, probably interfering with the flow of blood through the vessel, and thus inducing the softening above noted. Smaller deposits of similar granulations existed in great abundance over the other portions of the base of the brain.

"The optic globes were not removed for examination, the father of the child being present.

"Dr. J. G. Richardson was kind enough to examine the deposits removed, and sent me the following report:

"I find on microscopic examination that the "little sago-like masses" visible in the pia mater of the portions of brain you left with me on the 8th instant are *true miliary tubercles*, being seated in the tunica adventitia of the arterioles and smaller arteries, and made up of oval and obtusely angular cells (sometimes exhibiting endogenous cell formation), arranged in a delicate network, each of whose meshes generally includes but a single cellular element."

GLEANINGS FROM OUR EXCHANGES.

TREATMENT OF PARAPHIMOSIS.—M. Bardinet suggests the following simple mode of reducing a paraphimosis. He passes between the prepuce and corona a blunt lever—the blunt end of an ordinary hair-pin answers well—one being placed in the upper, another at some nearly corresponding place beneath. The fingers are then used in drawing forward the prepuce by a sort of screwing movement, the hair-pin or other blunt instrument, such as the handle of an ordinary teaspoon, acting as a lever to slide the prepuce over.

IMPORTANCE OF THE PURITY OF CHLORAL HYDRATE.

—Dr. Oscar Liebreich has recently published a paper in the *Berliner Klinische Wochenschrift*, in which he calls attention to the important subject of the purity of chloral hydrate, and the effect which its deterioration may produce on the patient to whom it is administered, and on its reputation as a remedy. The case, he says, is different from that of such a substance as quinia, the adulteration of which will only reduce, but not pervert, the proper action of the drug. With chloral and other substances prepared by analogous chemical processes, the result of the manufacture may be the formation of compounds which, if administered, produce an altogether different result from that intended. The process of manufacture is one which requires great care; and it seems that it is at least difficult to insure the purity of chloral if made in large quantities. Liebig himself, who discovered it, never attempted to make more than a few grammes at once; and Dr. Liebreich was so convinced, when he brought it into notice as a medicinal agent, that purity was necessary for success, that the first supplies were made under his immediate superintendence. At present it is manufactured in various places, and the result is that in some parts of the continent, notably in Saxony and Switzerland, it has fallen into disrepute. Dr. Liebreich has made a collection of specimens of the drug used in cases where it has failed to produce its proper action, and possesses, he says, some horrible chemical compounds which he would not venture to give to a human being. He prefers the crystallized form of chloral hydrate, as the most stable. It may contain hydrochloric acid: this is no disadvantage if the proportion remain the same; but if it increase it indicates that the formation of dangerous compounds may be going on. Sometimes the hypnotic action is increased: this he attributes to the production of chlorine compounds, which are more readily changed into chloroform than chloral itself is. An acid reaction arising from the formation of trichloroacetic acid does not show that the chloral is unfit for use, though it weakens its action. In pure chloral this action is limited, while impure chloral is liable to the constantly-increasing production of acid compounds—not trichloroacetic acid—of a deleterious nature. Dr. Liebreich remarks that the German Pharmacopœia is in error in fixing the boiling-point of chloral hydrate at 95° Cent. (203° F.). This, he says, is correct for anhydrous chloral, but the boiling-point of chloral hydrate is not constant.—*Brit. Med. Jour.*, March 21, 1874.

GUARANA IN CHRONIC RHEUMATISM.—Mr. E. A. Rawson states (*Irish Hospital Gazette*, April 15, 1874) that when suffering severely from lumbago, and other remedies failing, he tried guarana as an experiment. He took fifteen grains in hot water with cream and sugar, and experienced entire relief from pain for twenty-four hours. When the lumbago returned, he took another dose, with the same result. "I gradually," he says, "increased the dose to forty grains, and took it regularly once a day for about a week. The lumbago disappeared. I gave up the guarana, and in a few days the pain in the back returned. A forty-grain dose removed it, and it did not return for several days afterwards. Now, whenever it does, I have my remedy at hand. During the last month I have experimented largely with guarana on a variety of patients, rich and poor. The results vary. When the pain is acute, coming on with sharp stings, guarana acts like magic; when it is of a dull, aching character, the drug is slower in its action, and several doses must be taken before any decided benefit can be perceived.

"I have come to the following conclusions, viz.: that whenever the fibrous envelopes of nerves, the aponeurotic sheath of muscles, the fasciæ or tendons, are the

parts affected, guarana gives, if not instantaneous, at least very immediate relief, which will last from twelve to twenty-four hours; and I confidently expect that perseverance in the use of the drug, gradually increasing the dose up to forty grains, will entirely remove any of the above-mentioned kinds of rheumatism.

"Of the good effects of guarana on nervous hemicrania there is no doubt; and I trust it will prove in other hands as valuable against rheumatism as it has in mine."

TWO CASES OF ANÆSTHETIZATION DURING SLEEP.—Having read in the April number of your journal an article entitled, "Can a Person be Anæsthetized during Sleep?" it occurred to me that a brief report of two cases of successful chloroformization during sleep might prove interesting.

The first case was that of a little girl named Parsons, aged eight years. As a sequel to acute otitis media, the mastoid cells of one side became inflamed; and Dr. E. M. Curtis was invited to take charge of the little sufferer.

Deeming it expedient to operate for the evacuation of the pus as soon as convenient, we agreed to meet at nine o'clock of the following morning for this purpose. On our arrival, we learned that the patient had slept but little during the night, but was then sleeping sweetly. Chloroform was at once administered upon a four-by-six piece of surgeon's lint, held as near the child's mouth as possible without coming in actual contact. Not the slightest effort was made by the child to avoid the inhalation of the anæsthetic, and in a few moments she was well under its influence, and was immediately carried into an adjoining room and placed upon a lounge, where the doctor very soon completed the operation.

The child being still anæsthetized, the wound was dressed, and before she had fully gained consciousness we both left the room, having first given proper instructions to the parents. On making my evening visit, I was informed that my patient was not yet aware that she had undergone a severe surgical operation, or that either Dr. Curtis or myself had visited her on that day.

My second case occurred on the 15th inst., in the person of a little girl two and a half years old, named Drake, brought to me from Galena, Nevada, for the purpose of having a supernumerary toe removed from each of her feet. While waiting for the arrival of Dr. Nelson, who assisted me in the operation, the child fell asleep and was placed in the operating-chair. As soon as the doctor arrived, chloroform was administered in the manner already detailed in the former case, and with equal success, and the operation was soon completed without the occurrence of an unfavorable circumstance.

In the first case the condition of the child probably favored the ready induction of anæsthesia, while in the second, age alone could be supposed to have influenced the result.—*Dr. R. W. Clunes*, in *Pacific Med. and Surg. Jour.*

OPHTHALMOSCOPE IN THE DIAGNOSIS OF CEREBRAL TUMORS.—Dr. Fitzgerald publishes in the *Dublin Journal of Medical Sciences*, June, 1874, a communication on this subject, in which, after some preliminary remarks on the use of the ophthalmoscope in disease generally, he goes on to speak of the appearances presented by the optic nerve in cases of cerebral tumor. Von Graefe's description of the "stauungs papilla" is given in full. Following this, a case coming under Dr. Fitzgerald's observation is noted, and a chromo-lithograph given of the appearances presented in the retina. Dr. Fitzgerald then passes on to consider briefly the theories which have been put forward to account for the congested condition of the disk in cases of cerebral

tumor. After reviewing these, he remarks that an erroneous impression prevails in regard to Von Graefe's opinion of the diagnostic value of the stauungs papilla. Graefe did not regard this appearance as *absolutely* diagnostic of the presence of a cerebral tumor, but merely as the *expression* of increased intra-cranial pressure, and consequently whatever caused an increase of the pressure would also produce this swollen state of the disk.

To demonstrate the fact that this condition may be present in cases where there is no cerebral tumor, Dr. F. alludes to a drawing in his possession, taken from the retina of a patient suffering from meningitis, in which the appearances were quite characteristic. He concludes: "I am aware that an objection may here be urged, to the effect that if the same appearance can be produced by a cause other than tumor of the brain, such appearance is after all of very little practical value as a diagnostic sign. To this I would answer, that, apart from a most careful study of all the symptoms in any particular case, it can scarcely be looked upon as of any special diagnostic value; but that, on the other hand, due regard being paid to those symptoms, it must prove of invaluable assistance in forming a diagnosis."

Dr. Fitzgerald's article has been republished in pamphlet form by Fannin & Co., Dublin.

GALVANO-PUNCTURE IN ANEURISM (*Lancet*, July 18).—Dr. Anstie performed this operation recently at the Westminster Hospital in a case of abdominal aneurism, supposed to be connected with the coeliac axis. It had been treated for some time by means of subcutaneous injections of ergotin, after Langenbeck's method; thirty grains, altogether, having been injected, at intervals, during two days. This treatment having proved unavailing, galvano-puncture was performed, as follows. Two needles, insulated with vulcanite up to three-quarters of an inch of the points, were introduced into the aneurism at the most prominent part, and were then connected with the positive pole of the battery, which consisted at first of twelve Bunsen's cells, subsequently reduced to eight. The current was kept up for thirty minutes, during which time the patient suffered acute pain. Both needles were then cut short and left in the aneurism for twenty-three hours, when they were removed on account of redness and discoloration of the skin. The day after the operation the aneurism was firmer, and the pulsation appreciably diminished, the patient being quiet and composed. A subcutaneous injection of a third of a grain of morphia was given on the night of the operation, and another injection on the next morning. When last heard from, the patient continued in a very satisfactory state.

GLASS SYRINGES IN THE VAGINA.—SIR: It is very creditable to get broken glass syringes out of the vagina without damage to the patient or to the practitioner, but why did they allow their patients to use such instruments? Were it not that you have lately recorded two cases in which a glass syringe had broken in the vagina, and a third case in which death followed this accident,—were it not that I am occasionally consulted by patients who have been told to inject a weak solution of acetate of lead or of alum into the vagina, by means of a glass syringe, to cure uterine ulceration,—I should not think it worth while to enter a protest against the recommending of such instruments to patients. The danger attending the use of glass syringes for vaginal injections is evident, and their utter uselessness is no less clear; for, while the injection of two or three ounces of a solution of acetate of lead or alum can have little effect on a diseased womb, much good may be done by the injection of one or two pints of a similar solution, by means of one of the india-rubber siphon syringes sold by

all chemists. A glass syringe should only be used by the practitioner himself, when he wants to act on the vagina by a strong solution of nitrate of silver, or some similarly potent medicine.

I am, etc.,

EDWARD J. TILT.

—*British Medical Journal*, July 18, 1874.

ACNE ROSACEA.—Dr. W. B. Cheadle (*Practitioner*, July) takes Hebra's view of the pathology of this affection, in opposition to that of Wilson and Tilbury Fox. He does not regard it as an acne, the sebaceous glands being neither primarily affected nor in many instances involved at all. The essential morbid change does not consist in any inflammatory process, but in a new formation of vascular and connective tissues, the changes in the sebaceous glands being secondary or accidental. The conditions associated with its production are usually excessive indulgence in alcoholic drinks, gastric disorder, uterine derangements, and prolonged or frequent exposure of the face to heat or cold.

The manner in which these causes produce the particular effects observed is, Dr. C. thinks, by long-continued hyperæmia brought about by reflex action upon the local vascular system. An example of transient reflex action is seen in flushing of the face after a hearty meal or alcoholic indulgence; and it is this same effect persistently exercised which brings about morbid changes. Of course, as there is no true local inflammation, local remedies are generally useless. Stimulating applications—lotions of the perchloride of mercury, of sulphur, or of both, and applications of the acid nitrate of mercury—are the only local remedies which Dr. C. has found advantageous. Internal remedies which relieve the distention of vessels, saline purgatives for instance, are of use. Arguing from the pathology of the eruption, Dr. C. was led to apply faradization in several cases, and with the most encouraging results.

TAPE-WORM IN AN INFANT.—Dr. Dawosky relates a case of an infant six months old suffering from tape-worm. "After satisfying myself of the presence of the parasite," he writes, "I ordered a small dose of castor-oil daily for the child, and at the end of a week had the satisfaction of seeing the last piece of the worm, with the head attached, in the evacuations. The question now arises, how did the ovum of the tape-worm obtain ingress into the stomach of this child, which had only been nourished at the breast of the mother? Both parents were, as stated, in excellent health, and in neither of them could any traces of tape-worm be discovered. Dr. Weisse of St. Petersburg, the earnest defender and advocate of the meat-cure, states that he had in many instances observed tape-worm in children after the use of raw meat, and relates the case of a child eighteen months old. Yet in all these instances the source of the parasite could be traced. But how did the infant of six months, that had no nourishment but the breast of its mother, get the tape-worm?"—*Memoirabilien*, April, 1874.—*Baltimore Physician and Surgeon*.

UNUNITED FRACTURE OF THE THIGH TREATED BY THE INJECTION OF AMMONIA.—Bourguet has reported a case in which he has employed this treatment with success. A fracture of the diaphysis of the femur had not united after a period of five months. At this time ten drops of a solution of ammonia, in the proportion of one to three, were injected into the thigh, immediately about the extremity of the upper fragment. Four weeks later, twenty drops were injected about the lower fragment. Three days later a third was made between the fragments, and a week later a fourth of twenty drops, containing equal parts of ammonia and water. Within the next five weeks four injections were made with a solution of iodine and iodide of potassium. The

leg lay in a water-glass splint. The phosphate of calcium was given internally. Six months after the first injection the consolidation was complete and the callus very extensive. This is the second case that Bourguet has treated successfully in this way.—*Allg. Med. Central Ztg.*, 39, 1874.—*Medical Record*.

EXPLOSIVE MEDICINES.—Young medical men are warned (*Revue de Thérapie*, 1873) against combining in their prescriptions certain agents which in case of the development of any acid, or even if exposed to a moderately high temperature, are liable to go off. Among these dangerous formulæ may be cited a prescription for pills not unfrequently employed in England, composed of nitrate of silver, extract of nux vomica, muriate of morphia, conserve of roses, and extract of gentian, which, when affected by the development of heat, will speedily explode. In like manner, pills made of nitrate of silver and creasote, or carbohc acid, will very soon generate heat sufficient to induce spontaneous combustion. Still more surprising to the occupants of the sick-chamber is the energetic explosion (suggestive of nitro-glycerin) arising from the pills or mixtures of which oxymuriate of potash forms an ingredient.—*Clinic*.

SUDDEN DEATH FROM EMBOLISM OF THE PULMONARY ARTERY AFTER INFLAMMATION OF VARICOSE VEINS (*The Edinburgh Medical Journal*, May, 1874).—M. Chabenat gives the following conclusions on this important subject. 1. Inflammation of varicose veins of the adhesive type predisposes to embolism of the pulmonary artery, and, as a consequence, to sudden death. 2. The clot heaps up, and is carried on by the current of blood when the patient is in process of cure: it is generally the result of an effort. 3. Death is due in general to the size of the clot, which completely blocks up the pulmonary artery or one of its large branches. 4. The patient dies almost always without asphyxia, rarely by fainting. 5. As yet, we have no means by which to prevent the migration of the clots: it is therefore necessary as far as possible to prevent them from breaking up.

TETANUS FOLLOWING ABORTION (*The Medical Press and Circular*, June 10, 1874).—Mr. M. A. Boyd reports the case of a primipara, thin, anæmic, and nervous, in whom abortion was produced during the third month, by a fall. The hemorrhage was easily controlled, and the remains of the ovum came away entirely on the third day. She did well until the morning of the sixth day, when trismus made its appearance, together with the characteristic *risus sardonius*; opisthotonos followed on the next morning, with frequent and painful spasms, and her condition steadily grew worse until her death, which occurred six days after the commencement of the tetanic symptoms. She was treated with large doses of chloral,—nearly an ounce every twenty-four hours,—and with nutrients and stimulants. The tetanus was probably due to irritation of the brain, from deprivation of blood in an already anæmic subject.

BELLADONNA IN GOITRE (*Ibid.*).—Dr. R. T. Smith reports two cases of exophthalmic goitre, which were relieved and almost cured by the free administration of tincture of belladonna, after the failure of nearly all other known remedies. He considers it possible that the relief was given primarily through the heart, the drug acting sedatively thereon.

INFLUENCE OF ALIMENTATION ON THE PROPORTION OF WHITE GLOBULES IN THE BLOOD (*Le Progrès Méd.*, June 20).—Dr. Wilbouchevitch had under his observation for some time a man who suffered from a stricture of the œsophagus. When first seen, the patient had lived for some time on a purely vegetable diet, but as he grew

better he was gradually enabled to eat more and more nitrogenous food. By carefully enumerating the corpuscles from time to time and comparing the results with those elsewhere obtained, Dr. W. has arrived at the conclusion that a purely vegetable diet has an evident influence in largely increasing the relative proportion of white corpuscles.

ARGYRIA (*Le Progrès Méd.*, June 13).—M. Duguet presented at a recent meeting of the Société de Biologie a patient whose face, chest, and arms presented a silver-gray tint, due to the absorption of nitrate of silver. The other parts of the body were free from discoloration, with the exception of the velum palati and pharynx, which were quite dark. The absorption was supposed to have followed repeated cauterizations of the pharynx with crayons of argenti nitrat., which had been practised some years previously.

URETHRAL FEVER (*The Practitioner*, May, 1874).—Dr. Leopold Dittel considers urethral fever a peculiar affection, caused by the reaction of the urinary organs and the sympathy of the system generally with the local lesion. He distinguishes three forms: 1, the nervous form, with pure reflex reaction; 2, fever caused by lesion of the urinary tube; and 3, the so-called morbid form, which is associated with disease of the kidneys and their pelves, and often ends fatally.

PHYSIOLOGICAL ACTION OF CHLORAL.—M. Byasson thinks that the longer duration of action of chloral compared with that of chloroform is due to the slowness of the chemical action, and that the difference in the physiological phenomena is explained by the intervention of formic acid produced at the same time as the chloroform, and acting under special condition.—*Acad. des Sciences*.

MISCELLANY.

AT a meeting of the Commissioners of Charities and Correction in New York, held during the last week in July, a resolution was introduced and passed reorganizing the Medical Board of Bellevue Hospital. This Board consists of nineteen members, twelve of whom have been removed from their positions by the terms of the resolution referred to. The names of these gentlemen are as follows: Drs. Isaac E. Taylor, Lewis A. Sayre, John J. Crane, John W. S. Gouley, B. Fordyce Barker, Frank H. Hamilton, Alexander R. Mott, Thomas M. Markoe, Austin Flint, Jr., William M. Polk, William T. Lusk, and E. G. Janeway. Of these, Drs. Crane, Sayre, and Taylor have been members of the Board for twenty years, and the majority of the others from five to fifteen years.

One would naturally suppose that the Commissioners had been influenced only by the most weighty reasons in taking such unusual and extraordinary action in regard to the hospital appointments. Thus far, however, no reason whatever has been assigned by them for this change. This action on the part of the Commissioners will seriously cripple the corps of instructors at the Bellevue Hospital Medical College, and, if persisted in, may result in the destruction of the school. It is darkly intimated that professional jealousies are at the bottom of this movement, and that the brilliant and rapid success of this school has made it altogether too dangerous a rival to older seats of medical learn-

ing. We can hardly believe that the profession of New York will countenance any such movement as that which has been hinted at, and we shall hope to hear that the force of medical opinion has induced the Commissioners to see the propriety of reconsidering their action.—*Boston Med. and Surg. Journal.*

A NEW MEDICAL JOURNAL.—The *Archives of Dermatology*, a quarterly journal of skin and venereal diseases, has been started in New York City, with L. Duncan Bulkley, A.M., M.D., as its editor.

The following gentlemen have consented to be collaborators, and have undertaken the Digest and Review Department: Drs. T. E. Satterthwaite, E. B. Bronson, F. P. Foster, F. D. Weisse, G. H. Fox, H. G. Piffard, and Geo. M. Beard, of New York; Drs. L. A. Duhring and A. Van Harlingen, of Philadelphia; and Drs. E. Wigglesworth, Jr., and Jas. C. White, of Boston, among whom Dermatology has been divided; and Drs. F. J. Bumstead, R. W. Taylor, F. R. Sturgis, E. L. Keyes, C. S. Bull, G. M. Lefferts, and R. F. Weir, who have charge of the branches embraced under Syphilis and Venereal Diseases. Subscription, \$3.00 a year.

CLARIFICATION OF TURBID WATER.—Sulphate of aluminium and potassium, alum, or chloride of aluminium have long been used for this purpose, since, as is known, these salts are decomposed in presence of the bicarbonates of calcium and magnesium, producing hydrate of alumina, which in precipitation carries with it the substances held in suspension. In place of these substances the ordinary perchloride of iron, or rather the polybasic perchloride, may be used. This salt introduced into turbid waters clears them with a rapidity equal to that of the aluminous salts. Four drops of the iron solution suffice ordinarily to clarify two quarts of water.

A SOMEWHAT novel case occurred at Lennoxtown, Stirling, on Thursday. A young cow had been grazing in a field in which rifle-practice had been going on. As the animal died very suddenly, a post-mortem was made, which disclosed the fact that it had been feeding upon the fragments of spent bullets, the stomach being loaded with twelve pounds of lead.—*Med. Press and Circular.*

NOTES AND QUERIES.

"THE REVIVAL OF LEARNING."

TO THE EDITOR OF THE PHILADELPHIA MEDICAL TIMES:

As a specimen of the educational advantages which some of our Philadelphia medical students have enjoyed, allow me to submit the following "choice selections" from the ——— Hospital dispensary record:

"Henry Devlin, *Ireland, varacos vains*,—lead water x opii."

After writing the above, it is evident that our embryo Æsculapius consulted his Duglison, for on the next page was the entry "*Vara Cose Vains*."

One of his patients was afflicted with "*abscess*," and was treated by a "*poltis*."

Another, suffering from an "*intis ud*," was also treated by a "*poltis*."

A third unfortunate was ordered to use a "*pick plast*."

I ask, my dear sir, is not this enough to raise the

GHOST OF NOAH WEBSTER?

PHILADELPHIA, August 10, 1874.

OFFICE OF THE SUPERVISING SURGEON,
U. S. MARINE-HOSPITAL SERVICE,
TREASURY DEPARTMENT, August, 1874.

DOCTOR,—The Supervising Surgeon of the United States Marine-Hospital Service having been designated by Joint Resolution of the XLIIId Congress, approved March 25, 1874, in connection with a medical officer of the Army, "to confer with the health authorities and resident physicians of such towns [as were visited by the Cholera Epidemic of 1873], and to collect, so far as possible, all facts of importance with regard to such epidemic,"—for the purpose of making a report of the same to the President of the United States to be submitted to Congress,—I have the honor respectfully to solicit a detail of the facts which came under your observation concerning the propagation and spread of the disease during that year.

The following memorandum embraces, substantially, the points upon which information is desired:

1. Name, sex, and age of patient.
2. Residence of patient—town, street, and number.
3. Day and hour of attack.
4. Premonitory symptoms, their nature and duration.
5. Progress of the disease:
 - a. Day and hour of beginning of rice-water discharges.
 - b. Day and hour of beginning of cramps.
 - c. Day and hour of beginning of collapse.
 - d. Period and extent of suspension of renal function.
 - e. Nature of treatment and result.
 - f. Day and hour when convalescence began.
 - g. Day and hour when death occurred.
 - h. Post-mortem appearances in detail.
6. Story of house occupied, and height of floor from ground.
7. Sanitary condition of house and enclosure:
 - i. As to cleanliness of rooms—clean, neglected, filthy.
 - k. As to ventilation and light—good, defective, bad.
 - l. As to drainage of house—good, obstructed, absent.
 - m. As to drainage of ground—good, obstructed, absent.
 - n. As to location and condition of privies or water-closets, connection with street-sewer, mode of flushing, of ventilation of soil-pipe, disinfection, etc.
 - o. As to surface water, garbage, or filth about the premises.
8. Source and quality of water-supply. If from a well or cistern, proximity of privy, sewer, or drain thereto, and chance of pollution.
9. General topography of localities in a given town where cholera prevailed.
10. Character of soil.
11. Character of drainage.
12. Occupation and habits of patient, and whether a resident of house where attacked for two weeks or over.
13. The facts in any case where the patient was attacked within two weeks after removing from an infected district into one previously free from the disease, specifying the respective districts and character of exposure.
14. The sequence of cases where more than one was attended, with their relations to each other, and to the cases of other physicians, with names of such physicians.
15. The means and agents used by the physician, by the family, and by the municipal authorities to prevent the spread of the disease, and the result of such preventive measures.
16. Public measures taken to prevent the introduction of the disease into your community, with the result.
17. Temperature, rain-fall, and prevailing winds for as long a period as practicable prior to appearance of cholera, and also during its continuance.
18. Dates of first and last cases of cholera in the locality in 1873—total number of cases and mortality.
19. Connection, if any, between first cases in 1873, and the localities of the disease in the immediately preceding epidemic.
20. Names of cities, towns, and villages known to you where cholera occurred during 1873, with any facts relating to the introduction of the disease to such, and the address of some respectable practitioner residing in each of the places named.

Contributions to this investigation, by answers to the foregoing,—or to so much thereof as practicable,—will be fully acknowledged in the official report, the value of which, it is hardly necessary to say, will largely depend upon the co-operation of the profession thus sought.

Copies of any reports or papers which you may have already prepared on the subject, or of those prepared by others and annotated or amended by yourself, will also be of service, and may be forwarded, to be returned if desired.

I am, Doctor, very respectfully,

JNO. M. WOODWORTH,
Supervising Surgeon.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM AUGUST 11 TO AUGUST 17, 1874, INCLUSIVE.

HEIZMANN, C. L., ASSISTANT-SURGEON.—Assigned to duty with Expedition under Captain Anson Mills, 3d Cavalry, and, upon return of that command, to rejoin his proper station, Fort McPherson, Nebraska. S. O. 111, Department of the Platte, August 10, 1874.

LAUDERDALE, J. V., ASSISTANT-SURGEON.—Assigned to temporary duty at Fort Leavenworth, Kansas. S. O. 125, Department of the Missouri, August 10, 1874.

SATURDAY, AUGUST 29, 1874.

ORIGINAL COMMUNICATIONS.

AN INVESTIGATION INTO THE ACTION OF VERATRUM VIRIDE UPON THE CIRCULATION.

BY H. C. WOOD, JR., M.D.,

ASSISTED BY JOS. BERENS, M.D.

PART I.—VERATROIDIA.

(Continued from page 740.)

Section B.—Action on the Heart and its Nerves.

IT having been determined that the direct action of veratroidia upon the circulation is to lower the arterial pressure, and at the same time to slow the pulse, the question naturally arose, Does the alkaloid act directly upon the heart, or does it influence the latter slowly through the nervous centres? The following experiments were instituted to settle this point:

Experiment X.—A stout tomcat. During anæsthesia, opened the ascending cava and injected three-fourths of a grain of veratroidia (impure). There was an instantaneous arrest of respiration, followed at once by a violent general tetanic spasm, involving all the muscular system and the diaphragm. After the injection, the heart beat several times quite forcibly, though not nearly with the normal strength. Upon opening the thorax, the heart was found making vermicular contractions, which continued for some minutes. The venous pressure in the large veins was very decided, causing the blood to squirt from them when cut.

Experiment XI.—A large dog. One-tenth of a grain of pure veratroidia was injected into the femoral vein. The heart was immediately arrested in diastole, and, respiration occurring, became enormously dilated with blood. The auricles continued to pulsate. The left ventricle contained arterial blood, the right venous blood. The application of the strongest current to the surface of the heart, or by needles introduced into it, induced no contractions whatever.

Experiment XII.—A large cat. The spine was cut in the upper dorsal region, and a small hole was made in the chest, so that the finger could be inserted in such a way as to rest on the heart,—the animal being kept during the entire period anæsthetized. One-eightieth of a grain of veratroidia (impure) was injected into the femoral vein, without any very obvious effect. One-fortieth of a grain was then injected, with a similarly negative result. One-half of a grain was finally thrown into the vein, and the heart-beats at once commenced to slacken, and soon ceased. At the immediate autopsy the heart was found to be flabby and dilated. It refused entirely to respond to galvanic currents.

Experiment XIII.—A large terrier cur had his cord cut in the extreme upper dorsal or lower cervical region, and the par vagum also divided. The respiration was maintained artificially. The animal received various small doses of impure veratroidia, and finally one-fourth of a grain was thrown at once into the femoral vein. In a minute, or less, the pressure fell to nothing, and pulsations ceased. At the immediate autopsy the heart was found flabby and dilated. Galvanic currents had no perceptible effect upon it.

Experiment XIV.—A large cur dog had its cord cut in the upper dorsal (lower cervical?) region, and after-

wards its pneumogastrics. After small amounts of a very impure veratroidia had been exhibited, three half-grain injections were thrown, in as many minutes, into the femoral vein. The heart-movements ceased immediately after the last injection; the pressure in half a minute fell to ten, in another half-minute to zero. The strongest currents were unable to affect the cardiac muscle.

The above experiments, which have been confirmed at various times, certainly prove that veratroidia has a direct action upon the cardiac muscle: of course, those made after previous division of the cord and of the pneumogastrics, *i.e.*, after isolation of the heart, are the most satisfactory. In Experiment X. there is indeed no proof that the arrest was really the result of a direct action of the poison upon the cardiac muscle.

A fact which is indicated by the above experiments, and which is very obvious in the light of subsequent experimentation, is that very large doses of the alkaloid are required to affect the cardiac muscle,—doses much greater than are sufficient to kill, and very much greater than the minimum amount which will profoundly affect the respiration. It seemed probable, and subsequent experimentation has confirmed the surmise, that the drug has some action upon the heart besides that which it exerts directly on the cardiac muscle. In endeavoring to determine this, the first study was as to its influence upon the cardiac inhibitory nerves.

A reference to Experiment IV. or V. will show that an enormous reduction of the pulse follows the exhibition of veratroidia. Experiment further shows that this occurs when artificial respiration is kept up actively, and therefore that it is due not to an indirect action of the alkaloid, but to an influence exerted directly on the heart or its nerves. The reduction in the number of the pulse-rate may be due to an influence exerted upon the pneumogastrics, or may be the result of some other cause. To test this, the following experiments were undertaken:

Experiment XV.—A stout terrier. A small dose of woorari, just enough to quiet, given, and artificial respiration practised.

TIME.	DOSE.	PULSE.	REMARKS.
0 m.			Cut the pneumogastrics.
27 "		168	
30 "	gr. 1-40		Injected into the peritoneal cavity.
39 "	gr. 1-40		Injected into the peritoneal cavity.
47 "		189	

Experiment XVI.—A stout cur.

TIME.	DOSE.	PULSE.	REMARKS.
0 m			Cut the pneumogastrics.
26 "		176	
64 "		180	
76 "	gr. 1-40		
78 "	gr. 1-40		
82 "		164	
90 "	gr. 1-40	168	
104 "		212	
110 "	gr. 1-20	112	
113 "		204	

These two experiments are in accord in showing that doses of the drug which, in the uninjured dog, lower the pulse-rate very greatly, have no effect when the par vagum has been previously divided. Proof is thus afforded that the reduction of the pulse which is ordinarily present is brought about through the inhibitory nerves. Another method of getting the same result is by a division of the par vagum in the animal under the influence of the poison, as in the following experiments :

Experiment XVII.—A stout dog.

TIME.	DOSE.	PULSE.	REMARKS.
0 m.		68	
1 "	gr. 1-40		Injected into the carotid slowly.
3 "		44	
11 "		52	
12 "			Cut the pneumogastrics.
12 1/4 "		168	

This experiment is in accord with those previously given, and seems, with them, to establish the fact that the primary slowing of the cardiac beats by the drug is chiefly brought about by an action on the inhibitory cardiac nerves.

This being so, it is *a priori* to be expected that when the heart is freed from the influence of all the nerves antagonistic to the pneumogastrics, the results of the primary inhibitory impression should be very marked.

In order to test this point, the following experiments were performed :

Experiment XVIII.—A large cur dog. Veratroidia impure. The spine was cut in the lower cervical region.

TIME.	DOSE.	PULSE.	PRESSURE.	REMARKS.
0 m.		136	85-93	
3 "		122	35-40	
8 "				The fall is due to an extremely active artificial respiration. Artificial respiration regulated to thirty strokes of bellows per minute, and so kept during the rest of the experiment.
13 "		160	65-70	
14 "	gr. 1-30		65-70	One-thirtieth grain injected into femoral vein. Instantly the arterial pressure fell nearly to zero, and all movement ceased. No pulse could be felt in the exposed carotids or femorals, or motion of the heart through the chest-walls. About one minute after this, the pneumogastrics were cut, and instantly the pulse returned in the carotids and femorals.
31 "		168	50-60	

Experiment XIX.—A youngish cur, of moderate size. The cord was cut in the extreme upper dorsal or lower cervical region. After some time, one-fortieth of a grain of impure veratroidia was injected into the femoral vein. Before this, the mercury in the cardiometer had shown signs of the formation of a clot, but instantly after the injection the mercury fell very much, and after one or two very slow pulsations all movement ceased. The pneumogastrics were divided, but a clot prevented any movement of the mercury. On opening the chest, the heart was found to be in vigorous movement.

Experiment XX.—A powerful bull-dog.

TIME.	DOSE.	PULSE.	PRESSURE.	REMARKS.
0 m.				Spine cut in lower cervical region. Artificial respiration.
23 "			95-105	
26 "		56	90-100	
32 "		56		
38 "			90-105	
45 "	gr. 1-12			One-twelfth grain injected into the femoral vein. The mercury fell at once to 10 (equivalent to zero). No beat occurred for one or two seconds, then a succession of very distant, slow, and powerful beats, with a great rise of arterial pressure, followed by a greatly increased rapidity of heart's action. In a few seconds this high pressure gave way to a sudden slowing or stoppage of the pulse and fall of the pressure to 15; then slow, distant, very full beats (15 c. each), followed by a rise of pressure to 125, with a rapid pulse, then another fall, etc., as before. Alternations continuing, but not so marked as before. Injected as before.
49 "				
51 1/2 "	gr. 1-12		95-100	
51 3/4 "			20-35	
52 "			145-160	
52 1/4 "			30-33	
52 1/2 "			140-145	
52 3/4 "			50-60	
53 "				Same alternation of rise and fall. Into jugular.
54 "	gr. 1/2			
61 "			55-60	
62 1/2 "	gr. 1/2			Into jugular.
64 "		180	80-180	
70 "		168	40-50	There is no longer a marked rise or fall of the mercury or pulse. Both have been very steady at their present position for some minutes.
70 1/2 "				Par vagum cut.
71 1/2 "		168	55-60	
73 "			55-60	
79 "		168	50-60	Dog killed.

These experiments certainly are corroborative of the conclusions previously reached, namely, that the primary slowing of the pulse by veratroidia is due to a stimulant effect upon the inhibitory nerves. The vaso-motor nervous system having been paralyzed, and possibly the accelerators of the heart also, by the spinal section, full sway was left to the inhibitory nerves, and consequently in Experiment XVIII., where a minute dose of the alkaloid was thrown into the circulation, there was immediate diastolic arrest, and the singular phenomenon was offered of a heart, quiet, dilated, and seemingly dead, started into new life by division of the pneumogastric nerves,—*i.e.*, by removal of the inhibitory influence. The strength of the inhibitory apparatus is known to vary very much even in different individuals of the same species, and the diverse results reached in the last and the first of these experiments are merely instances of difference in degree and not in kind. The extraordinary rise and fall of the mercury in the cardiometer-tube, the incessant succession of cycles of diastolic cardiac arrest, prolongations of the beat, and hurried action of the heart, are explainable only upon the supposition that the inhibitory apparatus was intensely excited, but was unable to hold, as it were, the normal cardiac impulse completely in its power. The rapid alternations were, in other words, merely the varying phases of a struggle between the two forces or powers.

Upon examining the record of this last experiment, it will be seen that after the injection of a large dose of the alkaloid the alternations of low and high pressure ceased, and the mercury in the manometer became steady at a position much below normal. The most plausible explanation of this is that the excess of the poison changed a condition of inhibitory excitation into one of inhibitory paralysis, or, in other words, that whilst a small dose of veratroidia excites, a large one paralyzes the pneumogastriacs.

This explanation is strongly confirmed by the fact that coincident with the settling down of the pressure in the experiment just alluded to, there was a rise in the number of the pulse, and that section of the par vagum at this time did not affect the pulse-rate; a proof that the pneumogastriacs were really paralyzed.

In order, however, to establish beyond peradventure the truth of the proposition, the following experiments were performed:

Experiment XXI.—A very small dog.

TIME.	DOSE.	REMARKS.
0 m.	gr. I-40	Into femoral vein.
11 "	gr. I-40	" "
29 "	gr. I-20	" "
43 "	gr. I-20	" "
46 "		A current was applied to the pneumogastriacs (just cut), at first mild, afterwards very intense; no effect whatever was induced; the nerve was completely paralyzed.

Experiment XXII.—A young, stout pup.

TIME.	DOSE.	PULSE.	PRESSURE.	REMARKS.
0 m.	gr. I-40	130	90-100	Into femoral vein.
25 "	"			Cut pneumogastriacs.
25½ "	"	165	45-50	
28 "	"			Current to par vagum affected the heart very much.
32 "	gr. I-40		30-35	Into femoral vein.
34½ "	"	192		
35 "	"			Applied strong current to par vagum; no effect.
38 "	"	186	80-85	
40 "	"			Very strong current to par vagum.
40½ "	"	186	45-50	Current broken.
44 "	"		45-50	
65 "	"	186	38-52	Current applied to pneumogastriacs in the root of the neck where they had not been previously touched; no effect.

Experiment XXIII.—A stout terrier. Artificial respiration and small dose of woorari, just enough to quiet.

TIME.	DOSE.	PULSE.	PRESSURE.	REMARKS.
0 m.			85-95	
15 "	"		85-95	Cut pneumogastriacs.
21 "	"			Current applied to pneumogastriacs caused instant fall of pressure and prolonged diastolic arrest.
21½ "	"		15	
27 "	"	168	45-50	
30 "	gr. I-40		65-75	Injected into the peritoneal cavity.
39 "	gr. I-40		60-70	Injected as before.
47 "	"	189		

TIME.	DOSE.	PULSE.	PRESSURE.	REMARKS.
48 m.			15	Application of current as before caused diastolic arrest and fall.
53 "	gr. I-40		45-55	Into femoral vein.
61 "	"		20	Some fall under application of current to par vagum and slowing of pulse, but no diastolic arrest.
65 "	"		30-35	
68 "	"			A very intense current applied to the pneumogastriacs failed to influence the heart.

Experiment XXIV.

TIME.	DOSE.	PULSE.	PRESSURE.	REMARKS.
0 m.	gr. I-20		*15½-16	Artificial respiration resorted to, with exhibition of woorari in dose sufficient to keep the dog quiet.
6 "	"		10½-11	Injected into peritoneal cavity.
10 "	"			Pneumogastriacs cut. Canula changed to carotid artery.
20 "	"		10-12	
38 "	"		9-11	Under a strong current passed through the pneumogastriacs, which also slowed action of heart.
68 "	gr. I-10			Into peritoneal cavity.
90 "	"		9	Current applied to pneumogastriacs had no effect whatever. The arterial blood throughout this experiment was very dark and venous in appearance, owing to a leak in the bellows.

Experiment XXV.—A stout cur.

TIME.	DOSE.	PULSE.	PRESSURE.	REMARKS.
0 m.				Par vagum cut.
26 "	"	176	140-145	
48 "	"	0	0	Instant diastolic arrest from mild current to par vagum.
50 "	gr. I-40			Into femoral vein.
52 "	gr. I-20			Doubtful how much of these injections entered; some obstruction in the canula.
58 "	"	164	100-105	
64 "	gr. I-20	168	110-115	Into femoral vein.
75 "	"		85-90	Began artificial respiration.
84 "	gr. I-20	112	80-85	Into femoral vein.
91 "	"			Current of same strength as before to par vagum; at first no effect.
93 "	"	52	50-60	Current continued.
93¼ "	"			Current broken.
97 "	gr. I-20	84	75-80	
99 "	"	80	50-60	Very intense current applied to a freshly exposed portion of the pneumogastriacs, low down in the neck, had no effect whatever.

These experiments speak so plainly for themselves that a discussion of them is scarcely necessary. They are five in number, and in each case it will be noticed that after a full dose of the poison even the most intense faradaic currents applied to the pneumogastriacs failed to affect the heart. Every precaution was taken to prevent the possible fallacy of an exhaustion of the nerve by the current itself, and the teachings of the experiments must be received as final. It would have been very well to have tested the comparative sensibility of the par vagum before and after the injection of small doses

* In this experiment there was used a cardiometer with larger divisions of the scale than the one commonly employed.

of the poison, and thereby to have determined whether the inhibitory excitement primarily induced by such doses of the alkaloid is centric or peripheral. The doing of this, however, would have required an accurate determination of the minimum power of current required in the unpoisoned animal to influence the heart, and such determination necessitates the use of more delicate apparatus than was at hand. The final inhibitory paralysis is certainly peripheral; but whether the primary inhibitory stimulation is centric or peripheral must be left for other investigations to determine.

(To be continued.)

CONFLUENT SMALLPOX IN THE EIGHTH MONTH OF PREGNANCY—CHILD BORN WITH THE DISEASE—RECOVERY OF MOTHER AND CHILD.

BY A. TREGO SHERTZER, M.D.,

Baltimore, Md.

I WAS summoned to see Mrs. F., æt. 35, a regular patient, February 25, and found her suffering with the premonitory symptoms of smallpox: high fever, flushed countenance, throat slightly sore, loss of appetite, constipation, eyes injected, considerable pain in head and small of the back. She was eight and a half months advanced in pregnancy. After a careful examination, I ordered an ounce of castor-oil at once, and xylol. $\mathfrak{z}\text{i}$, mucil. acaciæ $\mathfrak{z}\text{ij}$. M. Sig., teaspoonful every four hours. After giving the general directions, and before leaving, I told Mr. F. the true state of affairs,—that in all probability his wife would miscarry, and that I might possibly lose both mother and child.

February 26.—I found Mrs. F. rather worse; she had not slept much during the night; bowels moved by oil; high fever, and no appetite. Ordered elix. val. ammon. $\mathfrak{z}\text{ij}$, morph. sulph. gr. ii. M. Sig., teaspoonful as required; with beef-tea, etc., and the same treatment to be continued.

February 27.—High fever and great thirst, for which I ordered a wineglassful of citrate of magnesia, three, four, or five times during the day. Slight eruption, and throat quite sore, for which I ordered a gargle; eyes sore and inflamed. Same treatment to be continued, and entire body to be sponged with hot vinegar and salt night and morning. Slept little during previous night.

February 28.—Rested badly; high fever, great thirst, tongue heavily coated, throat very sore, for which I used locally a solution of nitrate of silver, gr. x to aq. $\mathfrak{z}\text{i}$. Bowels constipated; entire person covered with eruption, and swollen. Same treatment continued, with the morphia mixture during the night, with beef-essence, brandy-and-water, and potassii chlor. $\mathfrak{z}\text{ss}$, pulv. alum. gr. xx, pulv. borac. gr. xx, sacch. albi $\mathfrak{z}\text{ss}$. M. Ft. chart. No. viii. Sig., one every four hours. I ordered a solution of elm to be applied to the eyes; also acid. carbolic. $\mathfrak{z}\text{i}$, oleum olivæ, glycerin, aa $\mathfrak{z}\text{iss}$. M. Sig., apply to face.

March 1.—Rested badly during previous night. High fever, great thirst; general appearance very puffy; literally covered with one mass of dark scabs; throat considerably ulcerated, and great difficulty in breathing and swallowing; complains of general pains, especially in abdominal region; eyes very sore, urine very high-colored and offensive, no appetite, and slight delirium. Applied a solution of nitrate of silver, gr. xx to aq. $\mathfrak{z}\text{i}$, to throat, and to continue powders. Con-

tinue the xylol mixture, with a wineglassful of citrate of magnesia every four hours. To have beef-essence with brandy-and-water. Tongue heavily coated and dry. Ordered the solution of elm to be kept over the eyes, and the mixture of carbolic acid, olive oil, and glycerin to be kept over the face, and the entire body to be sponged night and morning with hot vinegar and salt. Before leaving, I informed Mr. F. that his wife's case was assuming a very unfavorable aspect. At five o'clock same day I was sent for in haste, with a message that Mrs. F. was dying. My office being at least three miles distant, I drove in haste to her residence, and found her in a reclining position, gasping for breath. I saw at once the throat was closed, owing to the ulceration. Dipping the probang into the solution of nitrate of silver, I passed it down the throat, after which she spat out great flakes of muco-pus. Finding that her abdominal pains were greatly on the increase, I ordered hot hops and corn-meal poultices to be kept on the abdomen, and that the same treatment be continued, instructing Mr. F. how to use the probang.

March 2.—Rested very badly last night, although she took one grain of morph. sulph. in one ounce of elix. val. ammon. during the night. High fever, dry and coated tongue, and great thirst; whole body and face much swollen; eyes very sore and perfectly closed; throat very much ulcerated; general pains very severe, especially abdomen and thighs; tongue very dry and coated, mouth very sore; bowels opened during the night; urine very scanty, high-colored, and offensive. Continued same treatment, with poultices to abdomen, elm-solution to eyes; mopped her throat and sponged her off from head to feet with hot vinegar and salt.

March 3.—Little or no change in her condition; slept a little during the night, though quite delirious. Abdominal pains very severe. Continued same treatment, except morphia mixture; to have plenty of beef-essence and brandy-and-water. I told Mr. F. that it was very doubtful if I could save his wife, as her case was rather a hopeless one, and if the abdominal pains continued, to send for me, and I would rupture the membranes and deliver.

March 4.—With the use of heavy doses of brandy, slept well during the night; very little change in her condition; bowels moved. Continued the same treatment. At twelve o'clock at night Mr. F. came after me, stating that his wife was smothering, and the abdominal pains were so severe that she could not stand it. After cleaning her throat with the probang and solution of silver, I gave her half a grain of morphia and brandy, with the hot poultice to abdomen. After waiting some two hours, the pains continuing, I concluded to rupture the membranes and deliver; but upon finding her parts greatly swollen and sore, I concluded to give more morphia and brandy, and wait until morning.

March 5, 7 A.M.—Patient sound asleep. To have xylol mixture, beef-essence, hot poultices, and sponged. 6 P.M.—Patient much easier.

March 6.—Patient quite easy this morning. General appearance much better; rested some during the night. Bowels opened with the citrate of magnesia. Scabs commencing to fall off. To continue same treatment. The patient gradually improved, appetite returning.

March 8, 11 P.M.—I was sent for, and found her suffering with slight pains. I lay down in an adjoining room, and requested that I be called when wanted.

March 9.—At half-past eight o'clock regular pains came on. Prof. Byrd was sent for, who delivered her of a fully-developed son, which was literally covered with the eruption of smallpox. In due time—that is, in an hour or so after confinement—the infant was put to the breast, and the mother placed upon good, nourishing diet. From this time mother and infant commenced

to improve, and recovered, without a single trace of the disease, and they are now both living and doing well.

At the request of my friend Prof. Harvey L. Byrd, I took notes of the case, as we both considered it a very remarkable recovery.

A CASE OF PSEUDO-HYPERTROPHIC MUSCULAR PARALYSIS.

BY C. H. DRAKE, M.D.,

Scioto, Pa.

TO Duchenne of Boulogne belongs the honor of bringing this singular affection before the profession and giving to it a distinct clinical history. First applying the name "hypertrophic paraplegia of infancy," he afterwards substituted "pseudo-hypertrophic paralysis." Since then numerous observers have accurately described the disease, under various names. Niemeyer terms it "progressive muscular paralysis as a result of hypertrophy of the interstitial fatty tissue;" and Jaccoud proposes the term "progressive muscular sclerosis." The disease is evidently exceedingly rare, as but few cases have been placed on record. In this country the first recorded case is that of Drs. Ingalls and Webber (*Boston Med. and Surg. Journal*, Nov. 1870). Then a case by Dr. Pepper (*Phila. Med. Times*, June 15 and July 1, 1871). One by Dr. Mitchell (*Photographic Review*, Oct. 1871). One by E. M. Estrazulas (*Obstet. Journal of Great Britain and Ireland*, Am. Sup., page 81, Sept. 1873). Dr. Hammond (Treatise on Diseases of the Nervous System, 3d ed., page 699) describes one case as coming under his observation.

It is almost exclusively confined to children and young adults of the male sex.

The disease presents a curious train of symptoms, and when fully developed can scarcely be mistaken for or confounded with any other affection. In its incipency, however, the symptoms are obscure and the diagnosis difficult.

The following interesting case has been under my care for nearly a year. Various forms of treatment have been adopted and carefully carried out, but without apparent benefit, and the patient seems to be gradually losing ground.

A. B., 12 years of age, born in Monroe County, Pa.; mother healthy; father illegitimate, intemperate, always extremely eccentric in his habits, and for several years past quite insane. There is no history of syphilis, rheumatism, or gout. Two of patient's brothers died of what the mother calls "brain-fever," attended with convulsions; another died of consumption (?), two others of diphtheria, and another in infancy (cause of death not known). Six years ago the patient had a severe attack of "brain-fever," accompanied with violent and long-continued convulsions, and he has never enjoyed good health since. The present difficulty was first noticed about five years ago,—quite mild then; but he has gradually grown worse, so that now he can scarcely walk a short distance to school. His face and neck present no abnormal appearance, and he is quite cheerful. All the lateral and anterior abdominal muscles and those of the shoulders, back, and chest have undergone very great atrophic changes; there is marked sacro-lumbar incurvation, and when walking he throws the shoulders and

upper portion of the trunk far backward, balances himself on the metatarso-phalangeal articulations, elevates his heels, moves with a peculiar straddling step, can walk up a hill or stair only with great difficulty, and frequently pitches forward on his knees when attempting to increase his gait. When rising from a chair he throws the trunk forward, then grasps the thighs with his hands, and by a curious struggling movement assumes the erect position. His sleep is much disturbed, and he does not acquire knowledge as rapidly as other boys of his age; but his appetite is good, his bowels regular, the urinary secretion and body-temperature normal. There is increased action of the heart, amounting at times to severe palpitation, but there are no murmurs, and the ophthalmoscope reveals no changes in the fundus of the eyes. There is very decided hypertrophy of the muscles of the calves. Those of the fore-arms are also enlarged, but to a less degree, and quite recently I have noticed commencing enlargement of the muscles of the gluteal regions. The stomach and abdomen are distended and tympanitic, and there are large patches of dirty-brownish colorations on various parts of the body, giving the surface a marbled appearance. These patches are very irregular in form, are not sharply defined in their outline, but fade gradually into the natural color of the skin. His muscular strength is greatly impaired, being much less than that of his sister seven years of age. When eleven years and six months old he weighed sixty-one pounds. Quite recently (July, 1874) the following measurements were taken: height, 54 inches; right arm, greatest circumference, 6 inches; right fore-arm, greatest circumference, 6 inches; left arm, greatest circumference, 6 inches; left fore-arm, greatest circumference, 6½ inches; right thigh, greatest circumference, 12½ inches; right calf, greatest circumference, 13 inches; left thigh, greatest circumference, 12½ inches; left calf, greatest circumference, 12½ inches; around the buttocks, 23 inches.

There is a certain train of symptoms in pseudo-hypertrophic paralysis, more or less well marked, in every fully-developed case recorded; then there are other symptoms which are not constant, but are found only in certain cases. Mottling or coloration of the skin, for instance, which has been noticed in some of the cases described, in others did not exist. In Dr. Pepper's case, which, by the way, was a typical one, no change of color could be detected on any part of the surface. In the case of the lad A. B., however, there are a large number of irregular, ill-defined patches, some of them quite dark, and easily seen at a distance of ten or fifteen feet, while others are pale and indistinct. Nine months ago these spots were plainest over the stomach and abdomen, but they have gradually grown paler in these regions, while the skin over the pectoral muscles, which was of natural color when the patient was first seen, has assumed a muddy hue. I am inclined to the opinion that this mottling of the skin takes place only over the muscles while they are undergoing atrophic change, and that when this action ceases, and especially if a condition of pseudo-hypertrophy succeeds, the skin slowly assumes its normal color.

Apparent hypertrophy of certain muscles, usually those of the calves and fore-arms, is a prominent and very constant symptom. In the case of A. B. the gastrocnemii are greatly enlarged. They present a knotty appearance, and feel firm and elastic.

Anterior sacro-lumbar curvature, a tendency to

talipes equinus, and a slow wasting of certain muscles and groups of muscles, are seen in every instance. The walk is peculiar. Persons afflicted with this disease "waddle" along like a duck, and experience great difficulty in ascending elevations. My patient uses his arms quite as much as his legs in locomotion. He rapidly elevates and depresses them, like a gymnast walking a tight-rope.

At times he complains of pain of an acute character in the calves; aside from this he is free of pain, and has no tingling or sensation of numbness.

July 29, 1874.

CASE OF INFANTILE CONVULSIONS TREATED BY HYDRATE OF CHLORAL.

BY JAMES D. MCGAUGHEY, M.D.,

Wallingford, Conn.

I ATTENDED a case of eclampsia several weeks ago in a little child nineteen months old, healthy and well nourished, but of a hereditary super-sensitive nervous system. Several children of the same family died in convulsions. The parents are healthy, with the exception of a little malarial fever occasionally. The first time the child was attacked, several teeth were pressing upon the gums, which were promptly lanced; but the convulsions continued five or six hours afterwards. This first attack was severe, but was controlled principally by bromide of potassium and thorough bathing, with application to spine and antispasmodic injections. The little patient having some evidence of malaria about him as the exciting cause of the convulsions, and the fever being paroxysmal, I put him upon a quinine treatment, with marked improvement. In about a week the quinia was omitted and the child was attacked again with eclampsia, worse than ever. The convulsion seemed to be principally of the left side, and lasted from 6 P.M. until 6 A.M. without any intermission. I tried every measure I could possibly think of to relax the spasms: systematic bathing, nausea and vomiting were produced, the bowels were freely acted upon, stimulating and antispasmodic injections were administered, mustard and garlic to spine, ice to the head, bromide of potassium internally, also valerian and assafoetida, but all to no purpose: the spasms continued unabated; the child seemed to be getting worse, the skin growing hotter, pulse more rapid, and the clonic, almost tonic, rigidity of the muscles greater; the eyes were staring, with balls rolled up or oscillating from side to side. About three o'clock in the morning, all treatment having failed to produce any impression whatever, I determined to try chloral. I had never seen that article recommended in infantile convulsions, yet knowing its therapeutic power it seemed very reasonable to me that it would answer the purpose exactly, as I needed a prompt and efficient remedy. I was satisfied the child could not survive unless quickly relieved, and the longer the convulsions continued the greater subsequent danger and fear, even though the eclampsia should be controlled. I did not suc-

ceed in getting the medicine until near four o'clock. I gave the following prescription:

R Hydrat. chloral., gr. ij;
Fl. ext. valerian., fʒi;
Aquæ gaultheriæ, fʒiii;
Aquæ dest., q. s. ad ʒi.

Of this mixture I gave a teaspoonful every hour. I administered two doses, and the first perceptible effect I noticed was a relaxation of the spasm about the muscles of the eyes, the lids closing for a while, then reopening, followed by closing again, showing a tendency to sleep. The pulse became less frequent, and the skin somewhat cooler. The child being somewhat better, with a fair prospect of coming out of the convulsion, and being greatly fatigued myself, I gave some directions, and went home. After my departure, the father, seeing the good effects of the medicine, gave another teaspoonful, and in a short time the child was fast asleep, and awoke in an hour or two perfectly free from spasms.

This is the only case in which I have tried the chloral in infantile convulsions, but I think it is one which, considering the thorough treatment previous to its use, exhibits its wonderful powers in allaying spasms. Its effects were prompt and unmistakable. I think that in those cases of convulsions complicating whooping-cough and pneumonitis it will prove more successful than bromide of potassium.

DOUBLE VAGINA AND NECK OF THE UTERUS.

BY CHARLES D. GREEN, M.D.

MRS. A. L., from Sussex County, Delaware, while stopping in the city recently, was taken suddenly ill with uterine hemorrhage. She was 39 years of age. Her husband stated that they had been married eleven years, and this was her first pregnancy, and that neither of them had discovered anything unusual, more than that the vaginal canal was very narrow.

On making per-vaginam examination, I found a tumor occupying the vaginal passage, but could not at first make out its precise character, as I could not discover the os uteri,—in fact, could not find any approach to the natural formation.

Between the labia and nymphæ on the right side, as high up as the meatus urinarius, I discovered an opening, which communicated with a large space where was lodged a foetal mass, and above this the neck of the uterus. I enlarged this opening by pushing my finger forward, and found near the neck a communication with the second vagina which I had first examined. The septum separating the two canals extended from the vulva to the os uteri, four and a half to five inches in length and one-fourth of an inch thick.

The vagina that was continuous with the neck of the uterus could not admit the passage of the foetus, whilst the one which corresponded with the well-formed vulva terminated in a cul-de-sac.

Close to the neck, at the end of the septum,

there was a small opening, through which the semen had most probably found its way to the uterus.

The exhaustion of the woman from hemorrhage showed there was no time to lose, and I determined to divide the septum and remove the foetal mass. With a waxed thread and watch-spring, I passed Krammer's silver Eustachean catheter close up to the neck of the uterus, through the lateral fissure of the septum, then, turning its point towards the external opening, seized the thread with a forceps, and tied it firmly a quarter of an inch below the meatus urinarius. I passed a second thread in the same way and tied it as near as possible to the perineum, leaving between the two ligatures an interval of one-third of an inch for the division of the septum, which was divided with scissors on the point of my finger as far up as the neck of the uterus.

The cure was complete by the fifteenth day. At this time examination per vaginam revealed two openings leading to the neck of the uterus, united by a thin membrane, and so placed that after the finger is introduced into one opening the other is not perceived by the side of it. The uterus is single.

PHILADELPHIA, August 6, 1874.

THE "PINES" OF NEW JERSEY AS A RESIDENCE FOR PATIENTS WITH PULMONARY DISEASE.

BY JOHN R. STEVENSON, M.D.

AS the physician from Philadelphia rides over the Camden and Atlantic Railroad on his way to the "city by the sea," he notices, after an hour's ride, a remarkable change in the appearance of the country. From well-cultivated fields, interspersed with patches of fine forest-trees, he emerges gradually, as he approaches the station of Berlin, seventeen miles from the river, into a barren country where the white sand is covered with dwarf oaks (*Quercus elongata* and *triloba*), and pines (*Pinus inops*), and the huckleberry (*Vaccinium resinum* and *corymbosum*); and if it be the month of June, his eyes will be relieved by the bloom of the laurel and the magnolia. Through this country, dotted with here and there a settlement like an oasis in the desert, he rides for another hour until he emerges upon the meadows of the coast, and wonders for what purpose such a land was created, and whether nature's economy would not be better served if the whole of it were again sunk to the bottom of the ocean from which it came forth.

It is to this section of New Jersey, familiarly called by the natives the "Pines," that I wish to invite the attention of the profession. Geographically, it is the Atlantic slope of that State, which, beginning in the upper part of Cape May County in the south, extends in length ninety miles north to Monmouth County in the northeastern end of the State; and in width, from the sea-coast to the valley of the Delaware, a varying breadth, whose greatest distance is along the Camden and Atlantic Railroad, about forty miles. The valley of the lower Delaware, about eighteen to twenty miles wide, is separated from it by a ridge or elevation, whose greatest height is

about three hundred feet above the level of the sea; from this ridge water-courses run in two directions, the one leading to the Delaware River, the other to the ocean. This flat plain has a soil of coarse white sand, from six to twelve inches in depth, resting upon a bed of gravel or clay. It is abundantly supplied with water from numerous springs and rivulets, which in many places overflow the lower portions of the land, forming great swamps, which were originally covered with a growth of cypress (*Cupressus thyoides* and *disticha*), trees famous for their size and the durability of their wood, but are now mostly supplanted by the stunted oak and pine, through which still roam the deer and an occasional bear. The water of these springs and streams is peculiar, having a sweet pleasant taste and a brown or red color, giving to the hand, when thrust into it, the appearance of being bloody. It is called, in that country, "cedar-swamp water," and has the reputation there of being very healthy both to drink and to bathe in.

The climate is milder and more uniform than it is in the same parallel of latitude west of it, as the extreme heat of summer and cold of winter are materially modified by the proximity of the ocean and by the slope of the land to the southeast. This is shown not only by direct observation, but also by the character of the flora, which is essentially different from that of adjacent Pennsylvania, and is similar to that of Virginia and the Carolinas. A peculiarity about this locality is that malarial diseases are unknown, even along the streams and in the swamps, while in the Delaware valley malaria is prevalent, in a mild form, along all the water-courses that empty into that river.

From the earliest settlement of West Jersey, tradition has fixed in the minds of the natives a strong belief in the healthfulness of the "Pines," especially its beneficial effects upon diseases of the pulmonary organs; but as, until within a few years, the land, believed to be barren and worthless, was almost uninhabited except by wood-choppers and charcoal-burners, little was definitely known about it, except that occasionally an individual laboring under pulmonary disease, who was forced by business to spend some time there, found that his health had very rapidly improved.

The opening of the Camden and Atlantic Railroad, twenty years ago, and subsequently the building of the Cape May and the New Jersey Southern Railroads, furnishing facilities for reaching this country, induced an immigration into it, which proved two facts, one of which is that the land is highly productive for fruit, and the other that it is a desirable place of residence for sufferers with pulmonary complaints. The last has become so well known throughout some portions of our country, particularly in New England and Northern New York, that two large settlements—Hammonton, on the Camden and Atlantic Railroad, and Vineland, on the Cape May Railroad—have been formed largely of persons seeking this favorable climate for the relief of those affections.

My attention was called to these facts during 1863 and 1864, while acting as the examining sur-

geon in West Jersey for the government, to examine drafted men and volunteers for the army. During this time, about three-fourths of all the men between twenty-one and forty-five years of age, residing in that section of the "Pines" south of the line of Burlington County, came before me for physical examination, and were found to be remarkably free from pulmonary diseases, except the very large number of settlers who had moved there because suffering from them. I took especial pains to question them about their experience of the effects of the climate, and was almost invariably told that they had been greatly benefited, and many had entirely recovered. Since then, a number of cases have come under my observation of marked benefit resulting from a residence there; but space does not permit an account of them.

The professional testimony concerning the climatic influences of this section is limited, because, until recently, but few physicians lived in it; but those who have practised there say that pulmonary diseases are not common. Dr. John W. Snowden, of Waterford Works on the Camden and Atlantic Railroad, one of the most intelligent and accomplished physicians in the State, who has practised in the "Pines" for a quarter of a century, wrote to me a few years ago, in reply to inquiries upon this subject, that "phthisis is decidedly infrequent among our native population; chronic bronchial affections are not frequent; strangers laboring under pulmonary diseases are very decidedly benefited while here." Dr. W. L. Newell, of Millville, wrote, "I do not consider phthisis frequent among our native population. I would say the same of chronic bronchial affections generally." Dr. J. K. Pitney, formerly of Absecum, said substantially the same.

Why should this part of our country be peculiarly adapted to invalids with lung-diseases? An answer to this question might be inferred from the characteristics of the land as described above, but Dr. Snowden admirably states the causes which act beneficially. He says, "I consider the terebinthinate matter in the air, and with which the 'cedar-swamp water' is more or less impregnated,—the latter being drunk usually by invalids,—and the dryness of the atmosphere consequent upon a dry, sandy soil, as the chief causes of benefit in these cases. To these may be added a moderate climate, not subject to such great extremes of temperature as more inland territory, and immunity from malarial and other endemic diseases that weaken the body and thus frequently develop hereditary tubercles or hasten their fatal termination."

Having thus shown that we have a suitable climate for invalids with pulmonary diseases, close to the great cities of Philadelphia and New York, a few economic reasons why physicians in the Eastern and Middle States should recommend it over more distant and doubtful localities may not be out of place. The wealthy consumptive alone can visit Florida, Minnesota, and Colorado, and too often only to die away from home and friends; but in this part of New Jersey, where land can be bought for from five to twenty-five dollars per acre, he of moderate means

or of little means can take up his residence, have his family around him in his own home, with daily access to and from the business, schools, and other conveniences of the great cities, by means of the numerous railroads and the ever-increasing number of trains run over them. Chronic pulmonary disease cannot be cured by a short visit in a suitable climate, but only by a prolonged stay in it, and frequently a permanent residence alone will prevent a return of the complaint. There in the "Pines" will be found a cheap home and a healthy climate within easy reach of the pleasures and luxuries of the cities.

CHLORAL HYDRATE AND BROMIDE OF POTASSIUM IN SPASMODIC ASTHMA.

BY JULIO J. LAMADRID, M.D.

THE following two cases are of interest on account of the prompt and decided relief which the patients experienced. So far as I know, the above remedies have seldom or never been tried or given together.

On the 7th of January, 1874, I was called during the night to visit Mrs. Jacob B., aged 35. Upon arriving at the house I found the patient sitting at the edge of her bed, with her head and shoulders bent forward, and suffering with the usual symptoms of spasmodic asthma. In addition to this she would point to her hands and feet, showing that those parts were also affected by these spasmodic contractions or cramps. I gave her a hypodermic injection of the sulphates of morphia and atropia together (one-fourth of a grain of the former and one-ninety-sixth of the latter): this seemed to relieve her at once. I also prescribed for her a mixture containing some of the strongest antispasmodics of the materia medica. I called early next morning, but found that the patient was not much relieved. I then ordered a mixture of linimentum chloroformi (B. P.), oleum terebinthinæ, and tinct. capsici, to be rubbed well on her chest from time to time with the hand or a towel, and gave another hypodermic injection of morphia and atropia. At 10½ P.M. I was called again in a great hurry; her husband said she fell asleep soon after I left the house, and slept for three or four hours, and from that time seemed to be quite easy and comfortable, but about 9½ P.M. the dyspnœa came on again as bad as ever, if not worse. This time I advised her husband to throw the smoke of a cigar in her face: this seemed to relieve her so much that she insisted upon its repetition, but of course this could not last long. The smoke from some blotting-paper previously soaked in a solution of nitrate of potassium also gave relief for a time. This failing, I decided to give twenty grains of bromide of potassium and ten grains of chloral. I used the following formula:

℞ Chloral. hydrat., 3v;
Potassii bromid., ʒiiss;
Syr. flores aurantii,
Aq. dest., aa fʒi.—M.

Sig.—Take a teaspoonful in half a wineglass of water every two hours, until sleep is induced or dyspnœa is relieved.

In less than an hour the patient began to feel the effects of the remedy, and when the time came for her to take another dose she was almost free from the dyspnœa and the cramps; soon after taking the second dose the patient fell into a sound and peaceful sleep, which lasted till next morning. She continued the use of the bromide of potassium alone in ten-grain doses,

three times a day, for a few days, and since then she has been free from these attacks.

Case II.—Harriet S., aged 65, a widow, and mother of eleven children, sent for me on the 3d of July, 1874, at 10½ P.M. I found her laboring under a severe attack of spasmodic asthma, to which she was subject. A hypodermic injection of morphia and atropia and antispasmodics gave her some relief, so that she was able to sleep the rest of the night. The next morning at 9 A.M. she still complained of a little dyspnœa; advised to continue the antispasmodics. At 8 P.M. she had another attack; I now ordered the hydrate of chloral in fifteen-grain and the bromide of potassium in ten-grain doses, to be repeated in an hour if not relieved. She had slept all night after taking the second dose, and next day was feeling quite comfortable and free from the dyspnœa. She also continued taking the bromide of potassium alone, and as yet she has not had any more attacks.

NOTE.—Since writing the above for publication in the *Philadelphia Medical Times*, I have received the *Medical News and Library* for August 1, 1874, and *Braithwaite's Retrospect*. In either of these journals the readers of the *Medical Times* will find an article upon this subject. In the former, Dr. C. Theodore Williams (*British Medical Journal*, June 13, 1874) speaks very highly of chloral in asthma, and in the latter Dr. Anstie (*The Practitioner*, January 7, p. 19, 1874) remarks that bromide of potassium is a powerful remedy in spasmodic disease.

It seems, therefore, from the above remarks that my own observations or experiments are independent of any others made in this country, and that I may justly claim the priority of its use in this disease; while on the other hand the two articles already referred to will show and confirm the truth of my own statement, and the value of these two agents combined together in the treatment of spasmodic asthma.

BROOKLYN, July 7, 1874.

TRANSLATIONS.

PHYSIOLOGICAL RESULTS OF THE TRANSFUSION OF BLOOD (*Centralblatt für Chirurgie*).—A. Jakowicki endeavors to answer the following queries by experimental research:

1. As to the influence of blood transfused from the same species as compared with that of blood from animals of other species.
2. What influence has transfused blood the corpuscles of which have been destroyed, and what influence have solutions of hæmoglobin?
3. What is the relation of the fibrin-producing ferment in transfusion?

The experiments were conducted on cats and dogs, and, in the attempt to answer the first query, large quantities of blood were drawn from the vessels of an animal, and replaced by like quantities of defibrinated blood from animals of the same species. As the amount of blood which was allowed to remain in the vessels of the animal was too small to permit of the functions necessary to life being carried on, it was assumed that the defibrinated blood took this rôle. Exudations of the defibrinated blood into the tissue as observed by Magendie were not noticed in these experiments. In opposition to the results obtained by Gesellius in St. Petersburg in 1873, Jakowicki noticed that blood from animals of another species, whether intro-

duced just as drawn from the vessels of the animal or as defibrinated blood, speedily induced decomposition of the blood of the animal subjected to experiment. The urine soon became tinged with blood, as well as the fæces and the matters vomited. The color of the urine was not due to blood-corpuscles, but to coloring-matter of the blood in solution in the urine. If small quantities of foreign blood were injected, the urine gradually cleared up, lost its albumen, and returned to its normal state; while if blood of this character was injected in large amounts, the animals soon died. By the injection of serum, it was established that albumen found in the urine after transfusion must have its origin in the serum of the foreign blood injected.

In the experiments conducted to afford an answer to the second query, the solution of the blood-corpuscles was effected—1, by repeated freezing of the blood; 2, by agitation of the blood with small quantities of ether, and, 3, by agitation with water. In addition to blood altered by these methods, solutions of crystals of hæmoglobin were used. After injections of these fluids there was noticed in some cases the production of clots, but frequently there were no clots produced, but only those symptoms in a somewhat milder form which are also due to the injection of blood of other species of animals. From this it was concluded that the serum of foreign blood increased the deleterious influence of the dissolved coloring-matter of the blood.

In answer to the third query, he concludes—1, that even noticeable amounts of the solution of the ferment when injected into animals are not able to produce coagulation of the blood in the vessels of the living animal; 2, the longer the injected ferment remains in the blood the less is its quantity, and it is safe to suppose that at the expiration of twenty-four hours it has entirely vanished; but the blood still contains some ferment even for a considerable time after the performance of transfusion, and there is some present even when transfusion has not been performed; 3, the respiratory process does not appear to have any influence upon the elimination of the ferment; 4, it is not possible to find any ferment inducing the production of fibrin in the urine, but in that secretion there is found a ferment similar to diastase. The suggestion is made that the fibrin-producing ferment may be the original form of all the ferments of the animal organism, and that it may enter the glands with the blood, and there be converted into the specific ferments. W. A.

NEUROMA MULTIPLEX.—Prof. Kosinski gives (*Centralblatt für Chirurgie*) the following account of a case of neuroma which was treated by neurotomy with the happiest results. The patient, a man aged 30 years, was admitted into the hospital in March, 1872, on account of painful tubercles on the lower extremities. He then stated that the tubercles made their appearance in his sixteenth year, and were at first small and painless, but that later, when he, as a soldier, was compelled to make extended marches, they began to increase in size and to become painful. At the first examination it was found that the posterior and outer sides of the thigh down to the lower third, and also a portion of the surface of the buttocks, were covered with scattered tubercles, round or oval in shape, and varying in dimensions from the size of a pin's head to that of a hazel-nut.

These tubercles had their seat apparently in the corium, and were for the most part hard to the touch. The layers were, however, elastic and semi-transparent, and had their edges more sharply defined from the surrounding skin than those of smaller size. The skin covering them was dry and uneven, and covered with an epidermis which was more scaly than normal. When pressure was made upon the tubercles, more

especially upon the larger ones, intense radiating pain was caused, but when the patient was in a state of complete repose his sufferings were much less.

In order to find out the nature of these growths, which outwardly presented the appearance of tumors formed of connective tissue, two of the largest and most painful tubercles were cut out and examined with the microscope, and were found to be composed of nerve-fibres and connective tissue. The cutaneous endings of the nerve-fibres were in the tubercles, and the parts involved corresponded to the parts supplied by ramifications of the lesser ischiatic and a portion of the fibres of the external cutaneous nerves.

The medical treatment with mercury, iodine, etc., which had been attempted in this case, had proved entirely without effect; and as it was not possible to excise all the growths with the knife, or destroy them with caustics, it was determined to do away with the sensibility of the tubercles by the excision of a portion of the nerve-trunk whence the filaments supplying them were derived. In order to effect this, an oblique incision, running nearly in the direction of the gluteal fold, was made, and, the nerve having been reached, a portion of it, about one inch in length, was cut out. Preference was given to the oblique line of incision over the perpendicular, since it permitted the nerve-trunk to be found more readily. The immediate result of the operation was a loss of sensibility in the tubercles themselves, as well as in the region in which they were situated. Some of the tumors, however, especially those to the front and outer side of the thigh, still manifested sensibility, but to a less degree than before the operation. As the wound began to heal by granulation, the tubercles began to disappear, and this process went on with such rapidity that at the close of the four weeks which the patient spent in the ward, the larger tubercles were diminished to half their previous size, while those of smaller dimensions had vanished almost completely.

Four months later, it was found that this process of absorption had continued, and that the remains of the tubercles which still existed occasioned the patient no pain.

Prof. Kosinski thinks that this case is of interest in the following respects: 1, the diagnosis could only be made with certainty by the aid of the microscope; 2, that so far as his knowledge extends there is no case of neurotomy with tumors of this character upon record; and, 3, the results of the operation were so far in excess of his expectation. The rapid disappearance of the tumors consequent upon the nerve-section may also be of interest to the physiologist, since it points out the influence of the sensory nerves upon the nutrition of the tissues.

W. A.

TREATMENT OF PHIMOSIS BY MEANS OF THE GALVANIC CAUTERY (*Gazette des Hôpitaux*).—Amussat now employs in the operation for phimosis the galvanic cautery, and six cases are reported, in each of which the operation was thus performed with some slight modification of the details. The patients were usually operated on in a sitting posture, but children were placed under the influence of chloroform and laid upon a bed. A shield of boxwood was passed between the prepuce and the upper surface of the glans penis, and a perforation of the prepuce was then made by means of a trocar of appropriate size. A platinum wire having been passed through the trocar, this instrument is to be withdrawn. An assistant then fixes the penis and the boxwood shield, the wire is connected with the galvanic apparatus, and the operator with the heated wire cuts through the foreskin from behind forward. It is not necessary to employ a trocar in the perforation of the prepuce; the same object can be attained by using a

curved needle through the eye of which the platinum wire has been passed. The wire, too, can be substituted by the bistoury used in galvano-caustic operations, and when this is employed the operator grasps the penis in the left hand and cuts through the prepuce upon the wooden shield from without inwards.

A linear separation of the prepuce can also be effected by placing it directly between the two branches of a galvanic forceps, about ten minutes being required for the operation when thus performed. This mode of operating is attended by no loss of blood, and the wound is usually healed at the expiration of from three to five weeks. As a rule it is only necessary to cut through the superior part of the foreskin; but if a lateral incision or division of the frænulum is needed it can be effected in a similar manner.

W. A.

INFLUENCE OF THE INHALATION OF CHLOROFORM BY THE PARTURIENT WOMAN UPON THE FÆTUS.—Zweifel (*Berlin. Klin. Wochenschrift*) has proved by examinations of the placenta and by examination of the urine of newly-born infants that chloroform given to the mother by inhalation can pass into the fetal circulation, and thus the child in utero may be chloroformed.

W. A.

THERAPEUTIC NOTES.

OTORRŒA.—M. Ménière recommends in "earache" the use of leeches, with the following solution:

R Aconitiæ, gr. i;
Aquæ, f3v.—M.

In chronic otorrhœa inject the external meatus freely with tepid water, and paint once a day with—

R Acid. carbolic., gr. i;
Glycerin., f3i.

Three to six drops of the following solution may be allowed to fall into the ear and remain for eight or ten minutes:

R Zinci sulph., gr. iv;
Glycerin., f3ii;
Aquæ, f3vi.—M.

When great vascularity of the bottom of the ear exists, or even when there is perforation of the tympanum, use—

R Plumbi acetat., gr. ss ad i;
Aquæ, f3ss.—M.

—*The Doctor*, August 1, 1874.

DIGITALIS IN THE TREATMENT OF HÆMOPTYSIS.—Dr. Reboul has been in the habit of using for some time past large doses of digitalis in the treatment of hæmoptysis. The formula employed by him is as follows:

R Pulv. digitalis, 3ss ad 3i;
Aquæ, 3viss.

Make an infusion, and add 3x syr. limonis. Dose, a tablespoonful every hour, to be suspended should nausea and vomiting supervene. This treatment is peculiarly efficacious in hæmoptysis occurring during the feverish stage of phthisis.

ANTI-SYPHILITIC GARGLE (*Langlébert*).—

R Tinct. iodinii, 3ss;
Aq. destillat., 3viss;
Syr. aurantii, 3iss.—M.

Useful in mucous patches and secondary ulcerations of the lips and buccal cavity. This gargle is preferable to those containing corrosive sublimate, which blacken the teeth. If the ulcerations are rebellious, they may be touched lightly with the acid nitrate of mercury.

PHILADELPHIA
MEDICAL TIMES.

A WEEKLY JOURNAL OF

MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY

J. B. LIPPINCOTT & CO.,

715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, AUGUST 29, 1874.

EDITORIAL.

WANTED—LEADERS FOR A NEW CRUSADE.

FEW of the folk-movements of modern times have made more noise, been urged more pertinaciously, or created more disgust, than the so-called "woman's-rights movement." With its ultra developments we sympathize no more closely than does the most conservative reader of the *Times*. Rooted in the very groundwork of the sexual characteristics of a typical man, it seems to us, must be an antipathy to the hard-featured, loud-tongued, masculine woman fitted by nature for the platform and the hustings. The perfect type of woman is undoubtedly feminine and domestic, and such alone nature ordains as attractive to the typical masculine man. By the moralist the extreme woman's-right movement must be looked upon with suspicion, as, if he be not blind, he sees how closely it approaches in the doctrines and the practices of some of its foremost promoters to the brutish creed of "free love." Yet, in spite of the repugnance so widely felt, in spite of the taint of impurity, the movement still appears to have vitality, and in a measure to prosper.

The reason of this is obvious. Undoubtedly women in the past have not had that which is their due, and if now in the family and during prosperity homage is generally yielded them, yet when adversity comes, and the woman is thrown upon her own

resources, the tale too often grows sad, and she enters too often upon the tragedy of a struggle for mere existence. The world may be hard, yet the heart of the world feels pity for the wrong and woe of classes; and it is the underlying sentiment that those women who are forced to earn their daily bread very generally lead a life of excessive unrequited toil and anxiety, which has given vitality to this woman's-rights movement. Every right-minded man must sympathize with any effort to open new avenues for suitable employment to women. The opposition to some specific movements having this intent certainly has arisen from the conviction that woman was unfitted by nature for the positions into which she was being forced, and from the belief that nothing but evil could in the long run result from the effort to put a square peg into a round hole.

Likely enough our readers have already surmised that we are approaching the subject of "women-doctors." In this, however, they are partially mistaken. It appears to us that the time for discussion of this subject has gone by: the experiment is being made, and by its results before the lay public the movement will stand or fall.

We may confess, in passing, to a want of faith in the general adaptability of the sex to the calling of the physician, but really desire to call attention to a very curious anomaly in connection with the matter. Loudly, pertinaciously, has the battle been fought for the sex to enable it to enter upon an employment which requires the coolest of heads and the calmest of nerves to meet its emergencies, the wisest of judgments to solve its problems, and great physical powers to pass through its toils and withstand its exposure. So true are these things, indeed, that the most violent advocate of women-doctors must acknowledge that the great bulk of professional work will always be done by men; that in the army and the navy, as well as in the civil life of many country districts, women can take practically no part, and that in the city they can occupy only a section of the ground.

Closely allied to the medical profession is one requiring no cool head and calm nerves for trying moments, no clear judgment for times of doubt, no physical powers to bear active toil and exposure; a profession well paid, sedentary, requiring for reasonable success only a fair measure of intelligence and some special training and education. Yet the male pharmacist sleeps the sleep of undisputed possession: no nightmare of Mrs. Partington's sweeping his sex from the old fields of labor breaks his rest; no vision of displacement haunts his day. With the

Mohammedan fatalist he can cry, Mawsh Awllaw! "God be praised!" as he views the quiet of his own domicile and the inroads upon those of his brethren.

Why this is, it is difficult to say. It is possible that some of the earliest promoters of the "woman-doctor movement" were women who preferred noise to quiet, publicity to domestic life, and the supposed *éclat* of the medical profession to the more retiring, if not less remunerative, work of the pharmacist.

Whatever the causes may have been, the fact remains that women-druggists do not exist in America; and we are glad to see that in England this new avenue of employment for the sex is opening up. The right of women, who have successfully passed the usual examinations, to receive certificates, to become licentiates of the Society of Apothecaries in England, and to practise as apothecaries, is fully recognized by the new Apothecaries Act passed by the British Parliament, which received the royal assent a few weeks since.

We can see no reason why the male druggist or druggist's clerk shall not be in great part replaced by his sister in the trade. It is true that we have known those who would not hesitate to trust their lives to female physicians declare, with strange inconsistency, that women-druggists would make mistakes; that they are not careful enough. The major certainly embraces the minor, and he or she who is not careful enough to become a druggist is still more unfit to be a physician.

It may be that a woman rarely or never makes bread twice alike, or two shirts that are exactly similar; but, even if it be true that in ordinary life woman is not so accurate as man, is it not equally true that the difference is more the result of diversity of training than of inherent personal characteristics? We firmly believe that women can be trained to be careful and accurate. The hand that untaught can be trusted with the poison at the bedside certainly can be educated to handle the same materials at the dispensing-counter.

Why should not women be admitted to our colleges of pharmacy? No nude anatomy, no discussion of sexual problems, nothing that need tinge the cheek of modesty, is necessary there; and side by side without taint and without even inconvenience ought it to be possible to co-educate the sexes in pharmacy and materia medica.

Let us trust that a little of that energy which has been employed in thrusting woman into those positions for which she is at least doubtfully fitted by nature may be diverted into this seemingly safe channel of effort.

CORRESPONDENCE.

TO THE EDITOR OF THE PHILADELPHIA MEDICAL TIMES:

DEAR SIR,—I have been incited by the very interesting record of the performances of the dog Carlo, to give your readers a brief account of an instance of remarkable guessing powers in a spaniel. The incident seems to necessitate the possession, in a high degree, of both imagination and reasoning powers by the brute. For the truth of the narration I can vouch. The dog was an exceedingly sagacious one, and had already been taught a number of English words, as hat, handkerchief, etc.,—going for those articles when sent. One evening, his master, sitting in a front chamber, said, "Now I will teach Sport to fetch my slippers," and, commencing to take off his boots, told the dog to go to the next room for those articles. Sport instantly set off, but brought a work-basket or some other indifferent article, and was sent back, only to bring a cushion. By this time the master had got off his boots, and when he said, "No, no," to Sport, the latter stood still for a minute or two, seemingly in thought, and then suddenly, his face lighting up, sprang, with a suppressed bark, into the next room, and in a moment came back wagging his tail, with a night-shirt in his mouth. The dog had frequently seen his master undressing, and had, without doubt, thought that taking off the boots was the commencement of that process, and reasoned that a *robe de nuit* was the desideratum. That his actions were not the result of a mere coincidental chance is shown by the circumstance that the night-shirt was kept, with other things, in a closed box on the top of a sort of rack, so that the dog to get it was forced to climb up to the box, raise the lid with his nose, and search out the garment from amidst the other things. It only remains to add that Sport learned, once for all, that night, what "Fetch my slippers" meant; not, however, until he had brought out nearly everything else in the room.

Yours, etc.,

H. C. WOOD, JR.

SELECTIONS.

PROLAPSE OF THE UMBILICAL CORD.

DR. GEORGE J. ENGELMANN sums up a paper (*The American Journal of Obstetrics*, August, 1874) as follows:—In conclusion, I will sum up in a few words the facts attained and the laws established by the examination of our prolapse cases.

The causes of the prolapse of the umbilical cord have mainly proved to be such circumstances as prevent the complete filling of the pelvic brim, and the close adaptation of the lower segment of the uterus to the presenting part. One of the more important of these circumstances is the shape of the presenting foetal part itself, and we thus find that foot-presentations are most frequently complicated by prolapse, whereas vertex-presentations are least threatened.

The foetal appendages are of secondary and minor importance: undue length of the cord, its marginal insertion, or attachment of the placenta low down in the

uterus, can never be direct causes of the accident; excess of liquor amnii is alone to be feared.

Some stress is to be laid on abnormality in shape and position of the womb, much more upon twin births. More dangerous than any of these is the contracted pelvis, which I have proved by measurements and numbers to be the main cause of prolapse of the funis, directly and indirectly; a fact hitherto generally accepted, but never as yet clearly established. Another such vague general statement, that the prolapse is by far more frequent among multiparæ than among primiparæ, our cases disprove; they show that primiparæ are, comparatively speaking, almost as frequently afflicted as multiparæ.

The law governing the location of the prolapse is of importance, and here for the first time touched upon: it will, I trust, be verified by the investigation of other observers.

The post-mortem examinations revealed only the lesions due to death from asphyxia, nothing characteristic for death caused by prolapse of the cord.

The prognosis we can give is somewhat better than generally allowed; most favorable for foot-presentations, after these for shoulder and transverse presentations, while vertex-presentations are more dangerous than any; the case being, under all circumstances, more threatening when occurring in a primipara.

In the treatment of our cases the high importance of the postural method has been developed, more as an adjuvant, however, than as a method in itself of dealing with the prolapse.

Version is comparatively the most successful of all operations, and should be more frequently resorted to when any choice of method is given, as in head-presentations: the application of the forceps and reposition of the cord are less to be relied upon; but, whatever may be the course determined upon, it must be borne in mind that the success of all operations by which we seek the preservation of the child whose life is threatened by compression of the prolapsed cord is in a measure dependent upon the judicious use of chloroform, its application to full surgical anæsthesia.

GLEANINGS FROM OUR EXCHANGES.

TREATMENT OF FRACTURES OF THE FEMUR BY IMMOVABLE APPARATUS (*New York Medical Journal*, August, 1874).—The proper treatment of broken bones is still an open question, for, while upon a few points there seem to be a concurrence of opinion and a final settlement of practice, upon many points opinion and practice continue to differ. Dr. Frank H. Hamilton, in an able paper on this subject, asserts that while at the present moment plaster of Paris dressings are especially under discussion, a difference of opinion exists more particularly in reference to the treatment of broken femurs by the continuous plaster roller, known generally as Mathieson's method, and introduced in 1852. The sudden and terrible accidents, such as gangrene, ulceration, delayed union, and deformity, which had frequently followed the previous use of a similar method, prevented the general adoption of this one; but twenty years having passed away, and a new generation arisen, "primary rollers," "apparatus immobile," and plaster, convey no apprehensions of danger and are readily accepted.

In 1871 Prof. Sands reported twenty-one cases of fracture of the femur treated by Mathieson's method, in eight of which there was no shortening, the maximum shortening being one inch; Dr. Bryant published twenty-three cases, thirteen of which are not shortened;

and in 1872 Dr. St. Johns recorded fifty cases, with an average shortening of one-third of an inch, and of the whole number eighteen united without any shortening. None of these gentlemen met with any serious accident, except one perineal slough. Dr. Hamilton states that in his experience the results have not proved equally satisfactory, and suggests as probable that the examination and measurement of many of these cases had been left to other and less experienced persons than the gentlemen who reported them. In all his own cases the examinations and measurements were made by himself, and were witnessed and confirmed by the house-surgeons or by some competent medical man. By these reports he seeks to attain two purposes: 1, as has already been intimated, to enable us to form an intelligent opinion of the actual and relative value of the plaster of Paris dressing as practised at Bellevue; and, 2, to determine what amount of shortening and deformity generally results from the treatment of fractures, at the present day, in the hands of our most experienced city surgeons.

In six cases of fracture of the femur treated with plaster of Paris, in persons from eleven to eighteen years of age, there resulted in two cases a shortening of five-eighths of an inch, in one three-fourths of an inch, in two one inch, and in one one and a half inch. In three of the cases there remained considerable deformity, and in two there was ankylosis. In twenty cases of fracture of the femur treated by plaster, in persons over eighteen years of age, the following results were obtained: perfect, 1; shortened three-eighths inch, 2; shortened one-half inch, 1; shortened five-eighths inch, 1; shortened three-fourths inch, 3; shortened one inch, 3; shortened one and one-eighth inch, 1; shortened one and one-fourth inch, 2; shortened one and three-fourths inch, 1; shortened two inches, 1; case of gangrene and death, 1. Average shortening in nineteen cases, more than three-fourths inch. In five cases there was ankylosis; in one, delayed union; in one, no union; in five, deformity; and in one, paralysis, abscess, and caries.

The surgeon has to depend in this method upon the perineum for counter-extension, and upon the heel and the top of the foot for extension,—dangerous parts upon which to make pressure. If the plaster becomes loose it has to remain so, or else the limb must be re-dressed in the same manner as at first. The gangrene which occasionally occurs is due to the cutting off of the superficial venous circulation by what is in effect an Es-march's bandage. Dr. Hamilton has found that his own methods of side-splints, adhesive plaster extension, pulley and weight in the adult, and a double thigh-splint in children, have given better results than has plaster of Paris.

He gives nine cases of fracture of the femur treated recently without plaster, and, like the fractures already reported, not selected, but taken in the order of their occurrence.

In no case was there any deformity or ankylosis. In four cases of eighteen years and under, three were perfect, and one had two-eighths of an inch shortening. In five over eighteen years of age, one inch was the maximum and three-eighths of an inch the least shortening. The average shortening of all nine cases was three-eighths of an inch. Dr. Hamilton makes the following remarks on the conditions of a faithful measurement of the thigh:

"The fact that a man walks without a halt is no evidence that there is no shortening of the limb. In this regard patients are very unequal; one, having a shortening of only half or three-quarters of an inch, will limp perceptibly; while another, with a shortening of one inch or even one inch and a half, may not limp at all. This has been observed repeatedly. Nor is it

any evidence that the limb is not shortened because, while lying in bed, the heel of the broken limb can be brought down to the level of the other. By pitching the pelvis, the spine remaining erect, the heel may be made to descend, in most persons, two inches or more.

"Measurements made from the symphysis pubis, or from the round end of the anterior superior spinous process, are unreliable.

"The patient should repose upon his back, upon an even surface, with his lower extremities as nearly as possible in a line with the axis of his body, the two wings of the pelvis being in the same horizontal (transverse) line.

"A flexible, graduated tape-line is to be preferred to the steel tape-measure. The foot being steadied by an assistant, the surgeon should put his thumb-nail against the line where it joins the ring, and push his nail into the skin just below the anterior superior spinous process of the ilium, pressing firmly up and back, the back of his nail resting upon the skin. In this way he obtains a fixed point, and he can obtain an exactly corresponding point upon the opposite side. Below, the measurement may be made from either malleolus, but the outer has the most defined extremity, and is generally preferred. In most cases, for some months after the close of the treatment there is some œdema about the ankle, which renders it necessary to use great care in determining the point of the malleolus. The thumb-nail of the opposite hand may be used for this purpose, resting vertically upon the skin (flat against the lower end of the malleolus).

"There are a few sources of error which cannot be avoided. Occasionally, but very rarely, the malleoli of the two limbs are of unequal length; and in a few very rare cases, one limb may be congenitally shorter than the other."

HYDATID OF THE BRAIN—EPILEPTIC CONVULSION—DEATH (*British Medical Journal*, August 1, 1874).—A girl æt. 17, an inmate of a reformatory for two years and a half, began to excite attention by her strange conduct. She would steal things, and secrete them under her bed without any object. She refused her food, or crumbled it up and hid it in her pockets. She would lie on the floor and sleep in the daytime, but at night was restless and noisy, disturbing the other inmates of the room. She told her companions that she was shamming, that she might be sent to a hospital. On one occasion she attempted to strangle herself with a piece of ribbon tied tightly round her neck.

As no actual disease could be discovered to account for this strange erratic conduct, it was attributed to hysteria, the result of amenorrhœa, she having menstruated but once.

One morning she arose as usual at six o'clock, dressed herself, and struck one of her companions without any provocation or apparent reason. She shortly afterwards fell on the floor in an epileptic fit, and died immediately. When the body was seen shortly afterwards, the face and neck were perfectly livid, with foam issuing from the mouth. The tongue was not bitten.

The following day a post-mortem examination of the head was made. The brain was quite healthy, the vessels very slightly congested, and there was no effusion; but, on exposing the lateral ventricles, on the floor of the right one, attached to the optic thalamus, was an hydatid cyst.

LEMON-JUICE IN DIPHTHERIA.—M. Revillout recommends (*Gaz. des Hôpitaux*, June 20) in the strongest terms the employment of large quantities of pure lemon-juice as a gargle. He says that he and his father have used it during eighteen years, and always with success, it being the most certain application yet known.—*Med. Times and Gazette*, June 27, 1874.

AN EXTRAORDINARY CASE (*N. Y. Medical Record*, Aug. 1).—The *Irish Hospital Gazette* records an extraordinary case recently brought before the Dublin Pathological Faculty by Professor R. W. Smith, of Dublin University. The disease under which the woman succumbed whose skeleton he exhibited was one of rare occurrence, and difficult alike to diagnose, treat, or even name. At the time of her death the woman was forty-five years old. Fifteen years previously she had been sent to jail for some offence, which was probably committed while insane, as shortly afterwards she was transferred to a lunatic-asylum. During the first ten years of her residence there nothing remarkable about her was noticed, and she was employed in washing the floors, etc. At the end of this period she ceased to be able to work, and was confined to bed for the remaining five years of her life, gradually becoming more feeble, and dwindling away in stature until she became about one-half the height she was originally. She did not complain of any pain; her limbs became coiled up in every possible shape, and she seemed gradually to disappear from off the face of the earth. She died, possibly, from constitutional disease of the osseous system. He (Professor Smith), however, looked upon the condition of the bones not as a disease, but as a manifestation of an as yet unknown diseased condition. Professor Smith had weighed all the bones individually; the total weight of the skeleton (including the cranium) was two and one-half pounds, which equalled about the fourth part of the weight of a child at birth. The bones were extremely light, soft, fragile, and atrophied in every respect. The number of fractures was prodigious. The ribs were in a hundred fragments. The head of the humerus was bent; the fibulæ were curved; the thigh-bones and pelvis were huddled up together; and the bones of the vertebræ thinned and worn away across the front of their bodies. The lower jaw was atrophied and broken into three fragments; the base of the skull was cribriform all through; and he (Professor Smith) believed that if the woman had lived longer not a vestige of a bone in her body would have been left. As to the nature of this disease, he (Professor Smith) believed that it was identical with rickets occurring in the adult; and although that opinion might appear heretical to some, yet he was glad to find that in the last volume of Trousseau's *Lectures on Clinical Medicine*, that distinguished author, had expressed his opinion that osteomalacia and rickets were one and the same disease.

INTRAVENOUS INJECTIONS OF CHLORAL (*The Doctor*, Aug. 1, 1874).—The proposal of M. Oré to inject a solution of chloral into the veins for the purpose of producing anæsthesia has given rise to some discussion.

M. Collin objects to any intravenous injection on the following grounds:

1. That any medicinal agent employed in such a manner may act in too decided a way upon the cardiac, muscular, or nervous system.

2. That the substance so injected might form microscopic clots capable of plugging the capillaries of the lung and producing grave and even mortal lesions.

On the other hand, M. Bucquoy believes, after experimental tests—

1. That the act of injection is innocuous when the vein is not denuded.

2. That chloral used in this manner is not more dangerous than chloroform.

ACETIC ACID SPRAY IN DIPHTHERIA.—According to the *New York Medical Record*, very satisfactory results have been obtained at the Charity Hospital, in the local treatment of diphtheria by the use of acetic acid, in solutions of varying strength, in the form of spray produced by the atomizer.

THE PRODUCTION OF ANÆSTHESIA DURING SLEEP.—Professor Dolbeau, after several series of experiments, feels justified in drawing a somewhat positive conclusion on the possibility of inducing anæsthesia during sleep. "Scientifically, it is difficult, but often possible, to render persons insensible by means of chloroform, who are in a state of natural sleep. Certain precautions, the employment of a very pure article, and great practice, are conditions that favor the success of the attempt. It is probable that certain subjects are absolutely refractory, that is, it is impossible to anæsthetize them, in spite of every precaution that can be taken. Others, on the contrary, and especially young children, easily undergo anæsthesia without being aroused from their sleep by the irritation which the anæsthetic produces in the air-passages. Under the criminal aspect, it is certain that chloroform administered to sleeping persons may facilitate the perpetration of certain crimes. It is, however, probable that the conditions favorable for anæsthesia will be rarely combined on the occasion of criminal attempt. But before the tribunals the expert should declare that it is possible, if not easy, to render a sleeping person sufficiently insensible by chloroform to allow of his becoming the victim of a criminal attempt."—*Missouri Clinical Record*, August 8, 1874.

HYPODERMIC INJECTION OF ERGOT IN VARICOCELE.—In a case of varicocele which had existed for a long time, Dr. Bertarelli, of Rome, injected a solution of ergotin under the skin of the scrotum. The solution consisted of ergotin, 1 gramme, water, with a little alcohol, 2 grammes. The patient was ordered to maintain absolute repose, and to make local application of cold compresses. The next day the varicosities had disappeared. The success was complete after another injection, which was attended by but slight local reaction.

Dr. Cittaglia had cured another case of varicocele by the same treatment. By the eighteenth day nearly all the varicosities had disappeared; and there was nothing but a slight induration of the corresponding testicle to be observed.—*Alm. di Terapie*, 1874, *Lo Sperimentale*, March, 1874.

CHLORHYDRATE OF TRIMETHYLAMIN IN RHEUMATIC FEVER.—A new successful instance of the above has been communicated to the Therapeutical Society of Paris, by Dr. Martineau. When called to the patient he found that the elbow had, since the morning, become red, enlarged, and painful; skin hot; pulse 90. Ten grains of the drug were administered. The next day a great improvement was noted. The pain in the elbow had entirely disappeared, and the pulse had fallen from 90 to 65. No crisis or cardiac complication had occurred. The same treatment had been equally successful in a similar attack a year previously.

ENEMATA OF BROMIDE OF POTASSIUM IN OBSTINATE VOMITING.—Dr. Girabetti (*Medical News and Library*, August 8, 1874) has obtained the very best results from the administration of enemata of bromide of potassium, in doses of from one-half to two drachms, in cases of obstinate vomiting attending the pregnant state. The same drug, also administered in enemata, has been very successful in the hands of Dr. Laborde, of Paris, in obstinate vomiting connected with disease of the stomach, liver, and intestines.—*Lancet*.

ACTION OF BROMIDE OF CAMPHOR.—From many experiments upon cats and guinea-pigs, Bourneville concludes that, even in small doses, the bromide of camphor depresses the temperature, and that this depression increases progressively as the dose is increased, to attain its maximum in those cases where the dose administered is sufficient to produce fatal results.—*Le Progrès Médical*, June 20.

SURGICAL ANÆSTHESIA.—M. Fornes (*Medical News and Library*, August, 1874), a French naval surgeon, urges the advantage of putting a patient asleep by administering chloral hydrate previously to his inhaling chloroform for the purpose of anæsthesia.—*Le Mouvement Médical*, June 27, 1874.

MISCELLANY.

LOUISE LATEAU AND THE DISEASE OF THE MYSTICS.—Dr. Charbonnier has lately brought under the notice of the Académie de Médecine in Paris the disease under which Louise Lateau, the famous ecstatic, is now laboring. In a general review of the so-called mystics, he demonstrates that two natural conditions are indispensable to reach the mystic stage: the one, to profess a religion of which incarnation is one of the fundamental principles, so as to allow man to represent his divinity according to the form which accords with his desires and the climate which he inhabits; secondly, to submit himself to a debilitating regimen, which, while diminishing the activity of his physical functions, suppresses the superior faculties of the soul, to the advantage of the imagination—the *folie du logis*. Among the Hindoos, as among the Christians, the ecstatic undergoes a long preparation, consisting, for the corporeal part, in proceedings likely to annihilate all the functions; and for the soul, in such as suppress the functions of relation and the exercise of the will, and in the concentration of all the strength in order to fix the attention on a single object. He says that ecstasy has never been produced at once and in a healthy subject. The history of all mystics bears witness to this; and Louise Lateau has appeared, once again to confirm this law,—a law which takes the occurrences which have lately taken place at Bois d'Hama from the category of the marvellous.

Louise Lateau, who began to show signs of the ecstatic state when about eighteen years old, was accustomed from her earliest infancy to the more than frugal regimen of the Hindoos,—to the enforced fasts of poverty, to privations of all kinds, watchings, fatigue, and, in fact, everything which could impede the functions of nutrition. On several occasions she has manifested true suspensions of functional action, characterized by the absence of urinal discharges, constipation, sleeplessness, spasms of the epigastrium, and complete want of appetite,—a group of symptoms which are often found assembled in Esquirol's observations respecting maniacs. The stoppage of the functions, this living mummification of the organs and tissues, sometimes lasts a month in Louise Lateau. Dr. Charbonnier believes this condition to be the same which is often met with in insane persons, who refuse to take nourishment with the greatest obstinacy.

When Louise Lateau had arrived at a certain stage of debility, she suffered from neuralgic attacks, the inseparable companions of an impoverishment of the blood in common with sleeplessness. *Sanguis moderator nervorum, sanguis somniferus*. These nervous

phenomena have followed a sequence parallel to the aggravation of the general condition: painful neuralgias of the face, headaches, transient troubles of the intellect, slight attacks of delirium. After enforced feeding, which is prolonged more than a month, and hemorrhages, first by the mouth, then by the womb, and afterwards from the feet, hallucinations attended with delirium came on, which lasted several days. Some weeks afterwards an ecstasy came on. Such was the progress of the phenomena.

Dr. Charbonnier, in an exhaustive memoir on the mystics which he has lately presented to the Academy, makes an abstract of the chapter in it relating to the ecstatic state, showing the modifications of the organs of those afflicted by this disease,—modifications which may explain how life is sustained, notwithstanding such prolonged abstinences, and which he terms the "substitution of organs,"—a law which, according to him, is intercalated between the law of Malthus and that of Darwin.

THE "ESCAPE-BOX."—It is stated in the reports of the different prisons of Paris that five or six thieves die annually in jail from the effects of swallowing this box. It is of polished steel, about three inches long, and contains turn screws, hammers, silk thread, and every implement necessary for escape. The box is easily swallowed, but sometimes refuses to glide along the intestinal canal as expected, and often causes death. When, however, it does reappear, the thief is in possession of implements with which he can saw through the thickest bars.

"THEY DO THESE THINGS MUCH BETTER IN FRANCE."—Last May, at Châteaudun, three vendors of a quack medicine were condemned in the criminal court,—one to three years' imprisonment, two to two years, and all three to pay a fine of five hundred francs each. They were convicted in ten instances, in which the total of their receipts had not reached the sum of seven hundred francs. They were tried for *swindling*.

"This is noble!" said I, clapping my hands together. —*Boston Medical and Surgical Journal*.

RABIES IN SHEEP.—Some three weeks ago a mad dog bit two sheep at Wigginton, near Tamworth. On Saturday week one of the sheep showed symptoms of rabies, which gradually increased in intensity until Tuesday, when the animal's suffering became so pitiful that it was killed. No similar symptoms have as yet appeared in the other sheep.—*Med. Press and Circular*.

NOTES AND QUERIES.

NOT A DISCOVERER.

DEARLY BELOVED EDITOR,—I was not the first to discover the virtues of chloral in puerperal convulsions; I was *not* the first to use it in the United States, not the first in Philadelphia, not even the first in C—St. Nor did I ever mention chloral in (ahem!) my address on obstetrics, etc., etc. In fact, O friend of my heart (I write this with tears in my eyes), I *never* used chloral in puerperal convulsions, because (*turpe dictu*) I never had a case of that disease.

Pray, Mr. Editor, are you acquainted with anybody else who *did not*

discover the redoubtable powers of chloral? If so, let me know by telegraph. By doing this you will convey some little consolation to one who is
NOT A DISCOVERER.

THE MEDICAL STAFF OF THE UNITED STATES ARMY.

TO THE EDITOR OF THE PHILADELPHIA MEDICAL TIMES:

SIR,—As one of the medical staff U.S.A., I heartily endorse the views of "A Medical Officer," as expressed in your valuable journal of July 4, 1874. My experience during many years of service I believe to be similar to his.

Assignments of medical officers according to rank are very rare for those below the rank of major, and for the latter also they are frequently not the fact. A rule of assignments based upon a recognition of the claims of seniority would remove a source of dissatisfaction that has long been felt, and not in the least ameliorated by seeing citizen-physicians, in many instances, in better, if not the best, positions.

I believe that claims specified by your correspondent would be respected more in our corps if it officially and socially recognized the rank of its commissioned officers; but since we officially know one another only by grade, and socially only by a civil title, it is not unnatural that army usage in the assignment of officers should not be applicable to them, and that, too, by members of our corps. But a year ago a medical officer gave expression to his views that "we are outsiders altogether." Where I am now on duty I am officially designated by my army rank. I have the same official recognition from all departments of the army except *my own*. Here is certainly room for reflection, since more rank is sought—and there are none others more entitled to it—at the hands of Congress, while we fail to honor that already conferred by a total disregard of it, giving force to the contemptuous remark that we "seek rank for its emoluments," as we "fail of the *esprit de corps* of officers of the army" by our own "failure of perception of the necessity of a proper respect for our army titles."

It is a great mistake that the line and the other staff corps are offended at the medical officers' use of their military rank in place of corps grade. Granted exceptions to prove the rule, and granted also that they are sufficiently numerous to be troublesome, yet since there is no recognition by the medical officers, as a corps, of their rank, the trouble is greater, as it is cited as a *cause* of opposition to those who presume to respect it. The offspring of ignorance and prejudice is not an obstacle while intelligence, respectability, and potent influence are a willing support.

RANK.

CAMP GASTON, CALIFORNIA, }
August 10, 1874.

TO THE EDITOR OF THE PHILADELPHIA MEDICAL TIMES:

I have read the many articles on "hydrophobia" lately published, and have been surprised at the statements made in regard to it by some medical gentlemen.

The idea that a dog can cause this disease when "excited" or angry, is certainly very remarkable, to say the least, and *facts* prove the contrary.

I have resided in this State for twenty-five years, and have never seen or heard of a "mad dog." I have seen numbers of persons of all ages bitten by dogs, and many dogs bitten by their kind.

The people of this State are made of material similar to that of which the people of the Atlantic States are made, and it is difficult to tell why you should have hydrophobia in Philadelphia and not in California, *if* dogs *which have no disease can produce it*.

If a dog can cause this in man when he is simply *excited*, why does he not cause it in other dogs likewise? Here there are hundreds of dogs belonging to the Indians, and, like the dogs of the East, they bite people and also each other.

The "imagination" theory will not do here, either. If this had any foundation, men would have hydrophobia in California, because they would sometimes *imagine* that they had it, and dogs and cattle would *never* have the disease, *because of the want of imagination*.

The fact that this disease does not exist here is well known, and the gentlemen who are making so much ado about "mad dogs" can ponder over it and account for it.

Respectfully,

T. T. CABAMIS, M.D., A.A.S., U.S.A.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY, FROM AUGUST 18 TO AUGUST 24, 1874, INCLUSIVE.

STEINMETZ, WILLIAM R., ASSISTANT-SURGEON.—Assigned to temporary duty at Fort McHenry, Md. S. O. 183, A.G.O., August 21, 1874.

SATURDAY, SEPTEMBER 5, 1874.

ORIGINAL COMMUNICATIONS.

AN INVESTIGATION INTO THE ACTION OF VERATRUM VIRIDE UPON THE CIRCULATION.

BY H. C. WOOD, JR., M.D.,

ASSISTED BY JOS. BERENS, M.D.

PART I.—VERATROIDIA.

(Concluded from page 756.)

Section C.—Action on the Vaso-Motor System.

FROM the evidence which has already been brought forward, it is very plain that veratroidia exerts a powerful influence upon the heart and its nerve-supply. The question as to its influence upon the vaso-motor nervous system is a separate one, but its answer is rendered more difficult by the cardiac action of the drug. There are evidently three or four sets of experiments, by the comparison of whose results light may be thrown upon the vaso-motor action of the alkaloid. First, experiments in which the drug is given to the uninjured animal, artificial respiration being maintained to avoid the influence of the altered breathing; second, experiments in which the heart is separated from the inhibitory centres; third, those in which vaso-motor paralysis is induced by section of the spine; fourth, those in which both the pneumogastrics and spine are cut.

To the first of these classes belong Experiments V., VI., and VII. A reference to them will show that the arterial pressure falls very decidedly under the influence of the drug. The mere reduction in the number of the pulse will in a measure account for this fall, but on examining closely the record of Experiment VII. it will be noticed that although the pulse was at first greatly reduced in number, yet afterwards the rate of the cardiac pulsations rose nearly to the pristine point, although the pressure was a good deal less than half what it was originally. The conclusion is logically inevitable that in large amounts veratroidia either weakens the cardiac muscles, or produces vaso-motor paralysis, or does both. In regard to its action in small doses, these experiments bear no evidence.

In order to decide the influence of the drug upon the arterial pressure after division of the pneumogastrics, the following experiments were instituted:

Experiment XXVI.—A stout terrier. Artificial respiration; woorari in just sufficient quantity to quier.

TIME.	DOSE.	PRESSURE.	REMARKS.
0 m.		85-95	Cut the pneumogastrics.
15 "		85-95	
16 "		120-130	
30 "	gr. 1-40	65-75	Injected into the peritoneal cavity.
34 "		65-75	
39 "	gr. 1-40	60-70	Injected into the peritoneal cavity.
53 "	gr. 1-40	45-55	Injected into the femoral vein.
53½ "		30	
54 "		50-60	
60 "		35-40	
65 "		30-35	

Experiment XXVII.—A stout cur. Pneumogastrics cut twenty-six minutes before the first note.

TIME.	DOSE.	PRESSURE.	REMARKS.
0 m.		140-145	Injected into femoral vein. Injected in vein. Owing to an accident, doubtful how much of these two injections entered the circulation.
3 "		145-150	
5 "		140-145	
39 "		137-140	
50 "	gr. 1-40		
52 "	gr. 1-20		
56 "		100-105	Into femoral vein. Artificial respiration imperfect. Artificial respiration very active.
59 "		110-112	
64 "	gr. 1-20	110-115	
78 "		120-140	
79½ "		75-85	
80½ "		90-95	Artificial respiration imperfect. Artificial respiration ceased. Artificial respiration renewed.
81½ "		50-60	
82 "		90-95	
82½ "			
83 "		170-175	
83½ "		100-103	
84 "		80-85	

These two experiments certainly show that, in full dose, veratroidia is capable of lowering the arterial pressure after section of the pneumogastrics, and also that small doses have but very slight effect under these circumstances.

Experiment XXVII. shows that this depression of the circulation is not due to actual paralysis. For at the eighty-second minute, when the arterial pressure was less than two-thirds its original amount, the carbonic acid which accumulated in the half-minute during which artificial respiration was interrupted was able nearly to double the pressure, driving the mercury far above its original point. This fact seems to indicate that the fall of pressure was not due to a vaso-motor paralysis, but to a sedative action on the cardiac muscle,—a sedative action which was soon overcome by the intense stimulation of the carbonic acid. Be this as it may, it is evident that if the fall of pressure be due solely to vaso-motor paralysis, it ought not to occur after division of the cord. To test this, the following experiments were performed:

Experiment XXVIII.—Dog.

TIME.	DOSE.	PULSE.	PRESSURE.	REMARKS.
0 m.		116	90-105	Spine cut in upper dorsal region. Artificial respiration applied. This is twenty-two minutes after cutting the spine.
6 "		120	75-80	Under more active artificial respiration.
8 "			95-100	Less active artificial respiration.
9 "			80-85	Pneumogastrics cut.
12 "		120	65-70	A current, at first mild and then intense, applied to freshly-exposed crural nerve, for a minute and a half. No effect on the arterial pressure.
14 "			75-80	
20 "		112	65-75	Into femoral vein.
26 "	gr. 1-20	118	60-65	
27 "			45-55	
28 "	gr. 1-20	120	55-65	Pressure sometimes rising to seventy. It is not certain how much of these last two injections reached the circulation.
31 "		120	45-65	Under very active artificial respiration.
32 "		100	40-45	
33 "		100	45-50	
35 "			45-50	

TIME.	DOSE.	PULSE.	PRESSURE.	REMARKS.
38 m.		108	35-40	
43 "		116		The tube has been put into carotid.
44 "		120	25-30	
46 "			210	Under galvanic current applied to the spine. There was a general intense spasm of all the muscles, but the pressure did not fall at once, when the current was broken, and the muscles became relaxed.
47½ "		200	180	A minute has elapsed since current was taken off.
47½ "			110-115	
49 "			170	Caused by the passage of a current through the body of the dog, producing violent muscular spasms. The pressure fell instantly when current was broken. This was repeated several times, with same result.

Experiment XXIX.—A large terrier cur. Cord cut in extreme upper dorsal region.

TIME.	DOSE.	PULSE.	PRESSURE.	REMARKS.
0 m.				Par vagum cut.
12 "		176	85-90	
13 "	gr. 1-10			Injected into femoral vein. Artificial respiration.
14 "			65-75	
16 "		170	60-70	
22 "	gr. 1-10		50-60	Into femoral vein.
23 "			55-65	
24 "			55-70	
31 "		176	45-48	
40 "		174	40-43	
45 "	gr. 1-10		30-35	Into femoral vein.
46 "		176	30-35	
47½ "		176	35-40	
56 "		176	40-41	
58 "			30-35	
65 "			60-65	
65½ "	gr. 1-6			Into jugular. Dropped a few seconds after injection to fifty at one bound, and rose again to seventy.
69 "	gr. 1-6		90-105	Into jugular. Fell as before to sixty.
70 "		200	60-65	
72 "			70-75	
73 "		184	85-90	Another injection of one-fourth grain into jugular was followed by a fall of the arterial pressure to nothing and cessation of pulsation. The heart refused to react to galvanism.

Experiment XXX.—A large cur dog. Veratroidia impure. Spine cut in the lower cervical or extreme upper dorsal region.

TIME.	DOSE.	PULSE.	PRESSURE.	REMARKS.
0 m.		136	85-93	
14 "	gr. 1-30		65-70	Injected into femoral vein.
28 "				Par vagum cut.
31 "	gr. 1-10	168	50-60	Into femoral vein.
34 "		162	50-60	
36 "			45-50	Lost some blood.
47 "	gr. 1-10	152	30-35	Into femoral vein.
48 "		128	30-35	
60 "		160	30-35	
61 "	gr. 1		30-35	
61½ "			50-55	
63 "		172	70-75, going to 80.	
64 "			75-85	
65 "		188	65-75	
66 "			65-70	
67 "	gr. ½			Into femoral.
68 "			55-65	
69 "	gr. ½	186	55-65	
69½ "			30-35	
70 "	gr. ½			
70½ "			50-55	Mercury then dropped at once to zero. The heart immediately afterwards at the autopsy was found incapable of responding to stimuli.

In studying these experiments, it will be perceived that in the first the arterial pressure under the influence of the poison fell very steadily and very decidedly up to the time when galvanism was applied to the spine, and the experiment, so far as it affects the point now under discussion, was ended. The second and third of these experiments (XXIX., XXX.) are in accord in that the pressure for a long time fell with sufficient regularity, but after the exhibition of enormous doses of the drug rose again, the rise being in each instance coincident with an increase in the pulse-rate. The explanation of this phenomenon is difficult. Any defect in the artificial respiration will, under the circumstances present in the experiments, give rise to an increased arterial pressure, and the increase which occurred may possibly have had such origin. The probabilities would seem to be, however, that the secondary rise of pressure was really caused by the drug. As the exact position at which the spine was divided was, unfortunately, not noted, it is barely possible that the point of section was below the position at which the accelerators of the heart are given off, and that the increased pulse-rate was due to a stimulation of these accelerators, the increased pressure being the result of the increased frequency of the heart-beats. Be these things as they may, it is certainly a fair deduction from the record—first, that the fall of pressure produced by veratroidia is not caused solely by its vaso-motor action; and second, that a study of the arterial pressure indicates that when used in moderate doses the alkaloid has very little influence upon the vaso-motor nervous system. In order, however, to test this matter more accurately, other experiments have been performed. It is well known that when a sensitive nerve or even a portion of the skin is irritated in the rabbit, a very great rise of arterial pressure is produced. In the dog the result is less constant, and in some cases the pressure even falls. The cause of this is the very great power and sensitiveness of the cardiac inhibitory nerves in the dog, for as the result of this sensitiveness and power the heart is depressed so much by the pain as more or less to overbalance the effect of the vaso-motor spasm. This is shown by the fact that the rise of pressure is very marked when an afferent nerve is irritated *after* section of the pneumogastriacs. The fact (see Exp. XXVIII.) that after section of the cord stimulation of a nerve is powerless to cause rise of pressure, shows that the latter is due to a vaso-motor spasm, and that the vaso-motor centres are placed above the cord.

In order to test the influence of veratroidia upon the vaso-motor centres, the following experiments in conformity with the above-mentioned facts were performed:

Experiment XXXI.—A stout bull-terrier pup.

TIME.	DOSE.	PRESSURE.	REMARKS.
0 m.	gr. 1-40		Injected into femoral vein.
25 "			Cut the pneumogastriacs.
29 "			

TIME.	DOSE.	PRESSURE.	REMARKS.
30 m.		35-40	
30¼ "		50-55	Rise due to momentary application of a mild current to crural nerve.
31 "		30-35	
32 " gr. 1-40		30-35	Injected into femoral vein.
40 "		35-40	
47 "			Strong current applied to a freshly-dissected crural nerve.
48 "		110	Current broken.
49 "		35-40	
71 " gr. 1-40			
80 "		25-29	
81½ "		35-38	The slight rise only effect of a very strong current applied to a large, freshly-dissected nerve.
84 "			Artificial respiration stopped.
84¾ "		135-195	

Experiment XXXII.—A stout terrier. Artificial respiration, and woorari, in quantity sufficient to keep dog quiet and nearly to suspend respiration for a time, injected into the veins.

TIME.	DOSE.	PRESSURE.	REMARKS.
0 m.			Pneumogastrics cut.
5 "		90-100	Strong current applied to crural nerve.
5½ "		120-130	
15 " gr. 1-40		65-75	Injected into peritoneal cavity.
24 " gr. 1-40		60-70	Injected into peritoneal cavity.
38 " gr. 1-40		45-55	Injected into femoral vein.
65 "		30-35	Strong current applied to crural nerve.
66 "		30-40	

These two experiments show that whilst the arterial pressure does rise when an afferent nerve is stimulated in a dog with divided pneumogastrics, after a dose sufficient gravely to imperil life, yet when artificial respiration is performed and very large doses of the drug exhibited, the arterial pressure does not respond to the irritation of a sensitive nerve: *i.e.*, small doses of veratroidia do not affect very decidedly the vaso-motor system, but large amounts do exert a directly depressing influence upon these centres.

In concluding this investigation upon the action of veratroidia on the circulation, the results arrived at may be summed up in a few words.

The action of this alkaloid upon the circulation is altogether subordinate to its influence upon the respiration.

In minute doses it stimulates the cardiac inhibitory nerves or nerve-centres, but when given in sufficiently large doses it finally paralyzes the peripheral inhibitory cardiac nerves.

It exerts some action upon the heart-muscle or the contained ganglia; this action is probably a sedative one, but it is very feeble, and is only distinctly perceptible when the drug is precipitated at once upon the heart, or when the dose given is much above that required to arrest respiration. To kill the heart-muscle very large amounts are required.

Upon the vaso-motor system veratroidia acts as a depressant, but its influence is feeble, much less intense than its action upon the pneumogastrics. When artificial respiration is maintained, it can be given in such doses as to paralyze the vaso-motor centres.

(To be continued.)

THE METHODS OF PERFORMING ELECTROLYSIS IN ANEURISMS, NÆVI, AND OTHER BENIGN TUMORS.

BY GEORGE M. BEARD, M.D.

THE success of the electrolytic procedure in aneurism, varicose veins, nævi, cystic and other benign tumors, depends on the method used. One may fail by one process and succeed by another, just as in any other surgical operation. The tendency has been to be satisfied with the mere employment of galvano-puncture, without regard to the method, and to accept the results, whether favorable or unfavorable, as serving to settle the question of the value or uselessness of electricity in surgery.

In electrolysis everything depends on the method; and with the same method, skill, care, and thoroughness may succeed when awkwardness, carelessness, and inattention fail utterly. The failure of electrolysis in any form of tumor, benign or malignant, is not to be counted a reproach until we know the actual method used and the character of the operator.

The method of electrolysis of the base or working up the base, that I have employed in the treatment of malignant tumors, I have elsewhere* described in detail. I have here to speak only of ordinary electrolysis, where the needles, insulated or non-insulated, are plunged directly into the tumor.

The errors that have been and are continually made in electrolytic operations begin and end in ignorance or forgetfulness of the laws and facts of electro-physics and electro-physiology, and especially of the former. No one can be a scientific and successful electro-surgeon without also being more or less of an electro-physicist.

ANEURISMS.

In the treatment of aneurism, the great end sought is coagulation. A knowledge of the differential action of the poles in producing coagulation is essential to an intelligent use of electricity in treating aneurism. Coagulation takes place at both poles of the galvanic current; that at the positive pole being small, black, and hard, and that at the negative being larger, softer, and of a yellowish color.

Aneurisms may be treated with greater or less success, according to their size and position, the condition of their walls, and general health of the patient, by either of the poles, or by both combined.

The best method for the majority of cases, certainly for aneurisms of any considerable size, is to use both poles, and a large number of needles that are insulated so that the current will not act on the walls of the aneurism. In the treatment of aneurism, especially, careful insulation is needed. The advantage of using both poles is twofold.

First, a double clot is formed, one at the positive and the other at the negative pole. Although the

* Archives of Electrology and Neurology, May, 1874.

negative clot is soft and yielding, still, in combination with the positive clot, it is of decided service in closing the aneurism; and, so far as I can ascertain, there is no evidence that embolism is ever caused thereby.

Secondly, the resistance is greatly reduced by placing needles connected with both poles in the sac, so that the electrolytic action is very much more effective than when one pole is placed on the surface of the body. The blood is the portion of the body that best conducts electricity; and when both poles are inside of the sac and near to each other, as of course they must be, a mild current will cause vigorous electrolysis. On the other hand, if one pole be applied by a wet sponge to some indifferent point on the surface, a strong current is needed to produce a clot, and a long operation; and, unless the sponge on the surface is occasionally moved, it would cause great pain; and if the patient is under an anæsthetic, a blister may be caused. As the negative pole is more painful than the positive when the positive alone is in the aneurism, the negative on the surface may be very uncomfortable even with a feeble current.

In the electrolytic treatment of aneurism, as in so many other electrical applications, it is an advantage to have a rheostat, so as gradually to let the current on or off without shock.

STATISTICS OF ANEURISM TREATED BY ELECTRICITY.

The published statistics of aneurism treated by electricity are of little or no value, and for two reasons. 1. They represent experiments made, in a large percentage of the cases, by those who are but little familiar with electro-physics or electro-physiology. Quite frequently the poles have been confounded, so that it is impossible to tell whether the positive or negative is used, and from many of the accounts it is impossible to tell even approximately the strength of current used.

2. The statistics are derived in part, at least, from cases that are reported too early. The temporary relief that results from the coagulum formed in the aneurism by the chemical action of the current has been interpreted as indicating a perfect recovery.

Some of the cases hastily reported as cured probably died soon after, if not before the account of their recovery was fully in print.

For these reasons I omit all the statistics that have appeared on this subject, preferring the general average opinion, so far as it can be obtained, of those surgeons and electro-therapeutists who are best qualified to speak on this subject.

My general conclusion, derived from many experiments on animals, from actual experience, and from a comparison of the various observations that have been made on the subject, is, that for those varieties of aneurism—such as the thoracic, abdominal, etc.—that cannot well be treated by the old methods, and in some cases for those that are accessible to other treatment, galvano-puncture, rightly performed, may be of great service in relieving the accompanying symptoms, and in prolonging life, and in some cases may effect a perfect and permanent cure.

VARICOSE VEINS.

Varicose veins were treated by galvano-puncture, after the manner of aneurisms, many years ago. For the treatment of varicose veins the positive pole would probably be better than the negative, or than both together, and for the reasons above given. The space within the enlarged vein is comparatively small, and the small clot made by the positive pole ought to be sufficient to obstruct the *flow* of blood. The positive clot would have the advantage of firmness, and embolism would be less likely to follow than after the use of the negative pole.

NÆVI—ERECTILE TUMORS—ANGEIOMATA—MOTHERS' MARKS.

This variety of tumors may be treated by the ordinary method of electrolysis, with a good probability of success, provided the conditions of success are skilfully observed.

It is first of all necessary to understand that to cure all forms of erectile tumors electrolytically without leaving any scar or trace is simply impossible. In many cases, and notably in those of larger size, and which are partly cutaneous and partly sub-cutaneous, sooner or later destruction of tissue is requisite to bring about a cure; and destruction of tissue after electrolysis, like destruction of tissue after the use of other agents, is followed by cicatrization.

When the nævus is small and superficial, then a mild electrolytic operation may be followed by a shrinking of the tumor and a rapid and permanent absorption of the débris without any scar; but such cases can hardly be said to constitute the majority. The scars following the electrolytic treatment of nævi may, however, rapidly disappear; at least, the little patient may in time entirely outgrow them.

It is necessary to be understood, in the second place, that the electrolytic operations for nævi, as for other kinds of morbid growths, are usually sufficiently painful to require some form of local or general anæsthesia. It is almost absolutely safe to give ether to young children; and the operation, even though it be but very short and but little painful, can be conducted far more successfully when the child is anæsthetized than when it is not. With adults, and sometimes with children, local anæsthesia by ether-spray is sufficient; but it is generally inferior to general anæsthesia. The struggles of the child to get free, its terror at the sight of the instruments, can all be saved by a carefully-administered anæsthetic.

The details of the operation differ with the size and character of the tumor. Success has followed the use of both poles in the tumor, or only one, while the connection is made by a sponge electrode on some indifferent point. If the tumor be small, and but one pole is used, it is better that it should be the positive, since the clot found at the positive pole, though small, is hard and firm. If the tumor be large, needles connected with both poles may be used. Whether one or more needles are to be used depends on the size of the tumor; but gen-

erally one needle connected with each pole is sufficient. If many needles are used, it is difficult to manage them; and some may fall out, and thus disturb the operation. It is better, as a rule, to take out the needle at different stages, and insert it in various parts, until the entire growth is acted upon. I have sometimes found it of advantage to reverse the current during the operation, so that all portions of the tumor may be acted on by both poles. Insulation of the needles is only required in the case of entirely subcutaneous tumors—where, as in the case of aneurism, it is desired to produce a coagulum (which may be slowly absorbed) without injury to the skin.

The length of the operation may range between five and twenty-five minutes, according to the strength of current used, the size of the needles, and the size of the tumor.

The great point in all electrolytic operations for *nævi* is to do just enough without doing too much. If the operation be not reasonably thorough, absorption will not take place, or the tumor may recur. If the operation be too extensive or prolonged, the destruction of tissue may be greater than is needed, and the subsequent cicatrization may amount to at least a temporary deformity. For very large and semi-subcutaneous *nævi*, that exhibit a tendency to spread in all directions, it is necessary to place the needles at or near the base of the tumor, and in the surrounding tissue, among the enlarging and tortuous vessels, in a manner somewhat resembling the method of electrolyzing the base of malignant tumors. If such tumors are treated timidly, no good result will come, and the operation may be several times repeated without satisfaction.

The advantages of the electrolytic procedure in *nævi* are these: 1. In small and superficial tumors the cure may be effected with little or no scar. On the face and other exposed parts of the body, this advantage is very great. 2. In the large *nævi*, and those which are partially or entirely subcutaneous, the liability of recurrence would be less, and probably the extent of the cicatrization would be less, than after the ordinary method of treating these growths.

GOITRES.

Goitres are to be treated by ordinary electrolysis with sharp, bayonet-shaped needles, which may be either insulated or non-insulated. Needles that are smoothly insulated can be inserted through the skin of the neck without very much more difficulty than non-insulated needles. But if the insulation be roughly put on, the difficulty in insertion may be very great. An advantage of non-insulated needles is that by the action which takes place in the skin around it the needle becomes loosened at the negative pole, and so can be pushed in still farther without difficulty. For goitres of all kinds, the negative pole is much preferable to the positive pole, and for the same reasons as in cystic and fibroid tumors. It is better not to connect any needle with the positive pole, but to complete the circuit by a sponge electrode applied over the surface of the tumor. There is no danger in inserting a needle

even into a small goitre to a considerable depth, say one or two inches. By great carelessness it would, I suppose, be possible to wound the carotid artery. I do not usually employ an anæsthetic in the operations on the neck. I find that the ether-spray, or the local application of a mixture of carbolic acid and ether, prevents, to a considerable extent, the pain of the introduction, which the patient much dreads, and which is really more severe than the pain of the electrolysis after the needles are in position.

In a few cases I have observed that the needles, when inserted in a goitre, cause, by reflex action, pain in the forehead; in other cases, nausea and a tendency to faintness are observed. The majority of patients do not fear an operation of more than from five to fifteen minutes, which may be repeated two or three times a week.

This purely electrolytic treatment may be varied by external galvanization and faradization, with strong currents.

There is no question that external galvanization and faradization with strong currents, both steady and interrupted, will cause a considerable reduction in the size of goitres; and even when these methods do not cause any perceptible diminution, they at least relieve the sense of pressure, the heaviness, and the sense of suffocation or of choking that goitres often cause. External electrization alone is not so satisfactory as electrolysis with needles.

The prognosis of goitre under electrical processes varies with the nature of the tumor. Those which are small and soft may disappear entirely and permanently. Those that are large, provided they are not too hard, may also entirely disappear. The cystic varieties also give a good prognosis. Those that are both very large and very hard may diminish a certain percentage, but they do not entirely disappear. The best method of estimating the results of treatment is to take measurements of the neck. Almost all goitres will go down more or less, and usually at the outset of the treatment. Afterwards they recede more and more slowly; and, even in those cases where the cure is complete, the last quarter will require more treatment than the first three quarters. This is true of all solid growths that are treated by electricity.

CYSTIC TUMORS.

Benign cystic tumors may be successfully treated by the ordinary method of electrolysis. I have treated a number of cases, small and large, and with excellent results. The object of the electrolytic procedure in benign cystics is, of course, very different from the object of the same procedure in *nævi*. The therapeutical action of the current on cystics is somewhat complex. 1. The fluid is decomposed. The gaseous products of this decomposition sometimes escape through the holes made by the needles. 2. The walls of the cyst are stimulated, so that the fluid is absorbed, and thus the tumor is caused to shrink. This is, in fact, the *rationale* of electrolysis in hydrocele. 3. Decomposition of the walls of the cysts. This takes place, of course, only when uninsulated needles are used. When

the needles are insulated near to the end, the walls of the cyst are not acted on. 4. Evacuation of the fluid contents of the cyst without decomposition. This result may follow puncture of any kind, even when no electricity is used. It is more likely to follow electrolysis with the negative needle, for the reason that the needle, when not insulated, acts on the walls of the cyst and enlarges the opening made by the needle.

In operating on cystic tumors by electrolysis, the best procedure is to insert needles connected with both poles. The positive needle may be kept fixed, while the negative is worked in various directions, so as to act upon all the inner surface of the cyst, and also to enlarge somewhat the hole made by the needle in the walls of the tumor, and thus allow free exit of the fluid or gases.

Large, long, cutting needles are usually preferable when the tumor is large; but for small tumors almost any kind of needle will answer.

Hydrocele is treated electrically on the same principle as cystic tumors. The mere evacuation of the fluid, or the electrolysis of it, accomplishes but little unless the secreting surface is acted on by the current.

FIBROIDS.

Fibroids are usually hard, and therefore slow to decompose under electricity. This is true of all fibroids, wherever situated,—in the neck or any portion of the periphery, or in the uterus. Inasmuch as they are not usually malignant, the method of electrolyzing the base is not needed. They are to be treated by ordinary electrolysis, needles connected with both poles being inserted in the tumor. The needles may be insulated or non-insulated, according to the situation of the tumor.

The behavior of fibroids after electrolysis is not generally satisfactory: the amount of decomposition, on account of the density and comparative dryness of the tissue, is but slight, and the subsequent shrinkage and atrophy are not so marked as in goitre or cystic growths.

If a current of sufficient strength be used, the patient being anæsthetized, suppuration may be excited, and, as a result of the destruction and loss of tissue, the tumor may become somewhat smaller.

Fibroids of the uterus are of sufficient importance to be specially considered. They may be treated electrolytically, either through the vagina or through the abdominal walls, according to the position.

The danger of creating peritonitis by thrusting needles through the abdominal walls is but slight, and if the needles are well insulated by rubber there is really no danger. The insulated part should, of course, go beyond the peritoneum.

Dr. Kimball, of Lowell, reports excellent results from treating fibroids in this way. My own observations in this direction have not been of the most encouraging nature. I have never seen a large and hard fibroid tumor disappear under electrolysis. Relief of pain, of neuralgia, of anæsthesia, and of many of the other attendant symptoms, I have many times obtained, but never a complete or approximate dispersion of the tumor.

LIPOMATA (FATTY TUMORS).

Ordinary surgical treatment with the knife is so successful for fatty tumors that electrolysis would hardly be indicated, even if it could accomplish as much and as easily as the knife. Fatty tumors are, of course, benign, and when operated on do not recur. Fat decomposes slowly and with difficulty, and is not subsequently absorbed, at least to any marked degree. I have experimented on a number of cases of fatty tumors, small and large; but, although some slight reduction in size can be gained, the results have never been satisfactory.

WHISKY AS AN ANTISEPTIC DRESSING.

BY J. L. SUESSEROTT, M.D.

IN fulfilment of a promise made to Prof. Wm. Pancoast at the meeting of the Pennsylvania Medical Society at Carlisle in June of last year, I desire to place on record my testimony as to the value of the above-named agent. And, lest I might be misunderstood as claiming priority in its use, I will state that in the *Glasgow Medical Journal* for February, 1870, Dr. D. Blair recommended the use of whisky as a surgical application, and gave his method of using it, as follows:

"To remove the foreign substances or clotted blood, the wound is first washed thoroughly with strong whisky; it is then closed with stitches if necessary, again bathed with whisky, and covered with a rag and bandage both saturated with the same fluid; and, finally, all is enveloped in gutta-percha tissue or oiled silk, and directions given to the attendants to wet the bandage from time to time with the spirits. As a rule, the first dressing is not disturbed for three or four days, and afterwards it is changed every day, or every second day, according to circumstances. The principal thing to be attended to is to have the bandage kept wet with the whisky,—but not *too wet*, or it will impede the progress of the cure. I have never seen *much* sloughing, and I have not once seen erysipelas occur in wounds treated in this way; probably because septic germs, if they exist at all, are not numerous in our hyperborean regions."

After giving the history of two or three cases, the doctor adds, "I have also used whisky as an application to bed-sores. When fever occurs epidemically in country districts and villages, especially in the Highlands, it generally causes a panic among the inhabitants. The dread of contagion is so great that occasionally no one will venture to undertake the duties of nurse. Under these circumstances bed-sores are of frequent occurrence. I have seen more than one case in which the os sacrum and coccyx were exposed from sloughing in typhus, and yet the patients recovered. The bed-sores were treated with linseed and oat-meal poultices, mixed with whisky, until the slough separated; then whisky lotions were applied.

"In cases of chronic and scrofulous abscess, I have used whisky as an injection, and find that it checks the discharges and hastens the cure. In a case of

scrofulous abscess of the hip-joint, I attribute the recovery of my patient to its having been used in this way. The pain and hectic before and for some time after the abscess was opened caused so much prostration that I had slight hopes of my patient's recovery. I persisted, however, in using the injection two or three times daily, bathed the whole limb often with spirits, and kept it wrapped in cotton-wadding and a bandage. The stomach for a time would not tolerate solid food of any kind, and even beef-tea provoked nausea. Notwithstanding, in an incredibly short time my patient rallied, and I had the pleasure of seeing him walk well, although the joint continued somewhat stiff.

"In a singular case of abscess situated beneath the muscles in front of the abdomen, which opened at the umbilicus, I was highly pleased with the result gained by these injections. The discharge obstinately continued, although I perseveringly applied for a considerable time poultices and lotions of different kinds. At last I resolved to inject with strong spirits, but, from the peculiar situation of the abscess, and fearing inflammation might supervene, I used it very cautiously at first; but, no unfavorable symptoms having followed the first application, by degrees it was used more freely—two or three syringefuls at a time repeated twice or thrice daily. In a few days there was a marked improvement, and soon the discharge ceased completely, and the patient is now well."

I trust I may be pardoned for quoting so largely from Dr. Blair, but in no words of mine could I more fully convey the results of my own experience or give stronger testimony as to the value of what to me would now be an almost indispensable agent.

In my opinion, the antiseptic properties of whisky are not all the virtues that it possesses. The gentle stimulation to the granulations on the one hand, and its cooling action by evaporation on the other, undoubtedly aid in a material degree in bringing about repair. Dr. Blair neglected to state that it is only the first application that is objected to or is in any appreciable degree felt by the patient. If the compress or bandage is kept moist with the spirits, a very grateful feeling is produced; and in cases where even considerable laceration has occurred, healing by *first intention* may be confidently expected. I could recount numerous cases that would bear me out in this assertion, but will let a few suffice.

Charles E., aged 60 years, a carpenter, about two years ago had his right fore-arm terribly lacerated by coming in contact with the revolving head of a planing-machine. The integuments and muscles of the back part of the fore-arm were torn in shreds; the limb was placed on a splint, the torn tissues were restored as nearly as possible to their places, kept *in situ* by isinglass-plaster, and supported by compresses saturated with strong whisky. In two weeks from the time of the accident, no suppuration having taken place, the splint was removed and my patient was at work. About a year after this occurrence the same patient had the back of his left hand thrown into the same machine. The result was that the articular ends of the second and third phalanges of three of his fingers were entirely knocked out, leaving the fingers hanging by the flexor tendons. Deeming it impossible to save more than a

stump of the hand, I was about to remove the dangling digits, against which procedure the patient strongly protested. Sympathizing with the now twice unfortunate man, and desiring to let the realization of the full extent of his maimed condition break upon him gradually, I procured three small splints, upon which I carefully laid the, as I was fully persuaded, lifeless fingers, secured them with isinglass-plaster, and placed the whole hand upon a heavy straw-board splint, with the full assurance, in my own mind, that even with the deodorizing effect of whisky, by the next day my very hopeful patient would be satisfied of the propriety of their removal. The part, or, I might more truly say, the whole hand, was kept saturated with my favorite fluid for external use, and, much to my surprise and gratification, on the following day I found the circulation re-established. The fingers were kept on small splints to prevent too much shortening. Granulations repaired the lost soft tissues almost entirely, and, the metacarpophalangeal articulation not having been injured, I had the extreme pleasure, at the end of four weeks, to see my patient, who, by the way, is a man of strong nerve, hard at work, with a very useful hand.

About the time of the first accident to this patient, Charlie W., a lad of about 12 years of age, ran into a mowing-machine. His left foot was cut off just at the top of his shoe, and the right one, it having been elevated in the act of running, was taken off through the tarsal bones. Assisted by Dr. E. N. Sensery, of this place, I shortened the bones of the left leg so as to procure sufficient covering, but we both concluded that by the removal of the cuboid bone of the right one we might hope to save the heel, and make the limb more useful; leaving it as in Chopart's or Symes's amputation. Even after the use of strong ligatures and contracting bands, we were not able to bring the tissues together, but were compelled to leave a surface of two and a half or three inches entirely exposed. Into this we packed patent lint, well saturated with whisky, satisfied that, with some suppuration, we might hope for a full repair of the parts. Suffice it to say that in an incredibly short space of time the parts were healed, without any want of covering to the stumps, and with the loss of not more than *one fluidounce of pus from both limbs*. Of this latter fact we were confident, as we did all the dressing ourselves.

I could report a half-dozen cases of equally interesting character, but have already trespassed too much on your space.

In conclusion, I would say that Dr. Blair's recommendation of this agent to the profession does not in the least refute the assertion of the venerable Solomon, that "There is nothing new under the sun;" for if we call to recollection the wonderful effects of the application of whisky and lily-leaves, and whisky and balsam-apple, by our mothers and grandmothers, we are forced to the conclusion that they, and other more ancient dames, from whom they learned the art, were unconsciously using an article of no little value, but that the credit was given to substances which only served as spongy compresses to retain the fluid. I have never used Dr. Hewson's dry-earth dressing; not that I think it has no virtue, for the high standing in the profession of him who recommends it is sufficient to satisfy me that it is valuable, but where one so much more convenient and pleasant to use is at hand, I would seek for nothing else.

CHAMBERSBURG, PA.

TRANSLATIONS.

PHYSIOLOGICAL RESEARCHES ON DIGESTION IN THE LARGE INTESTINE OF MAN.—Drs. Czerny and Latschenberger communicate to *Virchow's Archiv*, vol. lx., 1874, an account of certain experiments performed by them on a patient suffering from an abnormal anus, situated in the right inguinal region, on a level with the crest of the ilium. The rectum was completely separated from the rest of the intestine, so that nutritious enemata could be introduced and withdrawn without any danger of admixture. This condition had resulted from a strangulated hernia, which, having been operated upon, left behind three mucous orifices, separated in such a manner that the internal orifice corresponding to the termination of the large intestine could not receive any trace of fecal matter.

The portion of intestine serving for the experiments, measured from the anus with the aid of a flexible tube, was about eleven inches in length. It was directed away from the fistula, then backwards to the extent of about three inches, then directly down. This last portion, of about eight inches in length, was destined to serve for the experimental study of absorption.

The mucous membrane was completely insensible, and the prick of a needle failed to produce contraction. The use of the induced current was not followed by any effect, but on applying the continuous current lively contractions were produced, which lasted as long as the electrodes continued in contact with the mucous membrane. On introducing the finger into the orifice of the intestine, the latter could be observed to contract strongly, and the mucous membrane rapidly assumed a red color and poured out an abundant secretion.

Character of the Intestinal Juice.—The drops of pure intestinal juice are slightly opalescent, and enclose small masses of protoplasm, occasionally containing drops and globules of oily matter. On any irritation whatever being applied, epithelium becomes mixed with the intestinal juice, which grows turbid. The reaction of the latter, and of the mucus generally, is decidedly alkaline.

Method of Experiment.—The experiments on digestion were made either with the intestinal juice collected, and consequently outside of the intestinal tube, or within the latter itself. In the first case, the albuminous substances, the starch or fat, were placed, together with a certain quantity of the juice, in small test-glasses, the mouths of which were closed with cotton. They were then exposed for two or three hours to a temperature of 95° F.

The experiments on digestion and absorption in the large intestine were made as follows:

The various liquids were introduced into the intestine by means of a caoutchouc tube, one end of which was inserted into the fistulous orifice. When the experiment was terminated, the liquids were removed by the anus. In order to avoid all error, the solutions used were divided into four parts, one of which was introduced every second hour by the same tube, and when the experiment was concluded a certain amount of liquid was allowed to pass through the intestine, in order to remove any matters which might remain. The experiments were made with albuminous solutions, with white of egg, emulsions of fat, and starch.

Experiments in Digestion.—Small morsels of coagulated white of egg, exposed during three hours to the action of intestinal juice at a temperature of 95° F., showed no alteration even when the fragments had been washed with a solution containing one-half per cent. chloride of sodium. Flakes of fibrin submitted to the same conditions underwent no alteration. Olive-oil, beaten up for a long time with the fresh juice,

showed no sign of emulsification. Starch mixed with the juice and exposed whole hours to a temperature of 95° F. showed no trace of sugar. It should be remarked that the juice employed was procured from both the upper and the lower portion of the large intestine. A small bag of gauze filled with morsels of coagulated white of egg was placed in the intestine and allowed to remain there for two months. When removed at the end of that time, the fragments showed no sign of digestion, and were simply roughened a little on the exterior by the action of bacteriæ. From these experiments it was concluded that the action of the intestinal juice of the large intestine and of its mucus, so far as the digestion of coagulated or soluble albumen is concerned, is simply *nil*.

Experiments in Absorption.—To determine the capacity of the intestine for the absorption of water, about f3iv were introduced every fifteen minutes for some hours into the portion under examination. The result showed an absorption of some ten or twelve drachms of water in the space of seven hours.

Experiments made with albumen demonstrated that in the normal condition albumen dissolved in water is absorbed as such by the large intestine. This absorption takes place more rapidly the longer the albuminous solution remains in contact with the intestine. If the latter is irritated by mechanical action or otherwise, absorption becomes hindered or completely arrested. Chloride of sodium hinders absorption, but this salt, even when the intestine has been irritated and general absorption has ceased, continues to be absorbed. Albumen as contained in white of egg is not in a condition to be absorbed without difficulty.

Experiments made upon fatty substances prove that the large intestine absorbs these when they are presented in an emulsified condition; the absolute quantity absorbed is proportioned to the concentration of the emulsion; while on the other hand the relative amount absorbed is proportioned to the length of time during which the fat remains in contact with the absorptive surfaces.

Experiments made with starch show that this substance is absorbed by the large intestine when in a jellied condition; but up to the present time it is impossible to determine whether its absorption takes place while in the form of starch itself, or after previous conversion into sugar.

Conclusions.—The large intestine in man absorbs albumen in solution, as such, as well as emulsions of fat. Starch in jelly is also absorbed, but whether as such or in the form of sugar is not known. Chloride of sodium possesses the property of interfering with absorption, or even checking it completely.—*Archives Générales*, July, 1874. A. V. H.

TRAUMATIC EMPHYSEMA.—H. Fischer (*Sammlung Klinische Vorträge*, 1874, No. 65).—Traumatic emphysema arises most frequently from injuries of the lungs, more rarely from aspiration of the external air through wounds and from degeneration of the tissues (spontaneous emphysema). When the lungs are injured there is no emphysema of the skin, or at least it is of but circumscribed extent, as is also the case when the external wound of the thorax corresponds directly with the wound of the lungs, when the wound itself is of sufficient calibre. If, however, the lungs are injured, and the cavity of the thorax is opened by a narrow oblique wound, or if the wound, through the action of muscular fibres, assumes an irregular form, or if it contain torn bits of tissue or foreign bodies, there arises an emphysema of the skin of more extended dimensions. In such cases, during the act of inspiration little or no air enters through the external wound, but a proportionately larger quantity passes through the wound of the lung. During

expiration the wound of the lung closes, and the air which has collected in the thorax is driven into the meshes of the connective tissue in the neighborhood of the long and irregular canal of the wound. Then, too, traumatic emphysema may be due to injuries of the lung when there is no external wound present; for instance, in cases of fractured ribs when a fragment of a rib perforates the pleura and wounds the lung. Frequently in cases of this character the wound of the lung becomes closed by clotted blood or adhesive inflammation, and then no emphysema is caused. When portions of the lung which are adherent are injured by fractured ribs, or if the injured lung is drawn back into the subcutaneous wound by the elasticity of the rib, traumatic emphysema ensues, but pneumothorax is wanting. Traumatic emphysema may arise after contusions of the lungs not attended by fracture of the ribs, or only be due to powerful compression of the lungs while the escape of the air through the trachea is impeded. In all cases of this kind, contusions and small ruptures are caused in the lung-tissue, and first occasion an intralobular emphysema, which gradually extends to the root of the lung, and finally passes upward in the trachea and makes its appearance in the neck. Traumatic emphysema can also arise in cases in which the thorax alone is opened, the lung not being injured, since the air which has made its entrance into the thoracic cavity can be forced by the expanding lung into the subcutaneous and intermuscular connective tissue. In these cases the emphysema is usually unimportant, since the pneumothorax soon becomes of such high degree that the entire side of the chest upon which the wound is becomes motionless, and consequently no more air is forced into the meshes of the connective tissue by the movements of inspiration. In a similar manner to that due to injuries of the lungs, traumatic emphysema arises also from wounds of the larynx. In wounds of the intestine, emphysema is of rarer occurrence, since the gases for the most part escape into the cavity of the abdomen, and it is usual to see this complication only when the fixed part of the large intestine is wounded upon its posterior aspect. It is more common to see emphysema after the so-called inward rupture of the intestine in consequence of disease, as in cases of strangulation followed by gangrene of the gut. On the head a form of emphysema is met with which is due to the passage of air from the pharynx into the cavum tympani, and thence through the pores of the mastoid process into the tissues of the scalp.

Emphysema of the eyelids occurs frequently in cases of fracture of the bones of the face, when the fractures extend into the nasal and frontal cavities. This form of emphysema may also occur after rupture of the lachrymal sac from violent expiratory efforts, and sometimes after gangrenous ulcers of the mouth following measles, wounds of the buccal mucous membrane, or extraction of teeth. Traumatic emphysema due to the aspiration of the outer air through wounds occurs but rarely. In this category belongs emphysema arising after rupture of the œsophagus, in cases of long narrow wounds, and in cases of tenotomy and complicated fractures. Fischer has observed spontaneous emphysema due to degeneration of the tissues in five cases of fractures and severe contusions in which there were extravasations of blood of large size. It is due to the escape of gases into the connective tissue from the extravasated blood. This driving out of the gases from the blood is favored by the acid reaction of the muscles, which is due to the bruising and tearing which they have undergone. The air which has collected in the connective tissue is finally absorbed by the blood-vessels; some of it, however, vanishing by the same way that it came. There are no difficulties attending the

diagnosis of emphysema, but spontaneous emphysema is often confounded with gangrenous. In a majority of cases when due to trauma the occurrence of emphysema has no influence upon the prognosis, and no treatment is indicated. If increased dyspnoea, due to large quantities of air in the interstices of connective tissue, comes on, small punctures through the skin are advised. As a rule, however, cases of primitive emphysema do not require speedy operative interference, while the contrary practice is to be enforced in such as are gangrenous in their origin.

EXTIRPATION OF THE SCAPULA AND ARM.—Veit (*Inaug. Dissertation*) reports an operation of V. Langenbeck's, in which, in consequence of a round-cell sarcoma, starting from the head of the humerus and extending into the muscles of the thorax and the scapula, that bone and the arm were extirpated. The clavicle was first exposed by an oblique incision, and divided by a bone-forceps. By this procedure the subclavian artery was exposed; it was surrounded by a catgut ligature, and divided, as were also the subclavian vein and the brachial plexus of nerves. From the first incision, a second was then made to the lower angle of the scapula, the muscles dissected away, and finally a third incision was made through the axilla, meeting the second, and the scapula dissected out. The patient, a laborer, aged 17 years, reacted well at first, but died from a hemorrhage from the subclavian artery on the sixth day. At the autopsy it was found that the ligature had been applied close to the origin of the transversalis colli, so that the formation of a proper clot had not been possible. In the lungs were also found numerous metastatic deposits from the tumor.

SUBCUTANEOUS INJECTIONS OF AMMONIA IN MALIGNANT PUSTULE.—M. Collin read, at a recent meeting of the Académie de Médecine (*L'Abeille Méd.*, August 10, 1874), an account of certain experiments made by himself upon the action of this remedy. His conclusions may be briefly stated as follows: 1, ammonia can be borne in the veins in strong doses (perhaps in man forty-five drops), but it is possibly a sedative rather than a diffusible stimulant, as it abates the general temperature in certain cases to the extent of 2.5° Cent.; 2, it acts as an irritant when introduced into the cellular tissue; 3, it neither destroys nor neutralizes the virus of malignant pustule.

A. V. H.

THE USE OF THE CATHETER AFTER URETHROTOMY (*Milit. Med. Jour.*, 1873, vol. cxviii. p. 37).—In six cases upon which Dr. Kadoski performed internal urethrotomy, he was prevented from introducing the catheter after the operation, as he had intended doing, and from the results which he attained he is satisfied that it is not necessary to use catheters or bougies in these cases until several days after the operation. He thinks that by thus postponing the introduction of these instruments the urethra escapes much irritation, and the patient much pain, and that there is no danger of the stricture which has been divided reuniting.

W. A.

ONYCHIA MALIGNA.—Wilkomiski (*Mosk. Med. Ztg.*, 1873, No. 37) has used the nitrate of lead in cases of onychia maligna, with the best effects. All that remains of the diseased nail is to be removed with scissors, and the nitrate of lead, in substance, to be spread on the diseased surface, there being no necessity for the application of any bandage. The slough separates after a few days, leaving a clean surface, upon which a new nail forms. He describes five cases of the disease in each of which this application seemed to have a specific influence.

PHILADELPHIA MEDICAL TIMES.

A WEEKLY JOURNAL OF
MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY

J. B. LIPPINCOTT & CO.,

715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, SEPTEMBER 5, 1874.

EDITORIAL.

CORONERS' INQUESTS—SINGULAR VERDICTS.

THE loose and imperfect manner in which coroners' inquests are held in many parts of our country has often been the subject of just animadversion, both by the practitioner of medicine and the practitioner of law. When we call to mind the sort of *material* composing the great majority of coroners' juries, we need not be much surprised, but shall rather be amused, at some of their extraordinary verdicts; albeit these said verdicts do not reflect very creditably upon the medical man who is presumed to make the autopsy and to instruct the less-informed jury as to the true nature of the cause of the death.

Not very long ago a curious case of this kind occurred in the neighboring State of Delaware. A person died under very suspicious circumstances, strongly pointing to strychnia as the cause of death, and also indicating a certain individual as the homicidal agent. A post-mortem examination was made, but (as we are informed) no chemical analysis was instituted for the purpose of settling this all-important question. The adroit examiner, and the no less far-sighted jurors summoned on the inquest, arrived at the sapient conclusion—simply *from the inspection of the stomach*—that it was a case of *suicide*! Truly, a most comfortable conclusion for the suspected culprit.

About a month ago, a respectable man died very suddenly in this city, at Petry's restaurant,

corner of Walnut and Broad Streets, being found in a dying state on his bed in the morning. From the circumstance that he had complained the evening previous of being in great trouble, it was very naturally conjectured that the deceased had committed suicide by poison; but no evidence of this was furnished from the surroundings, such as the discovery of any bottle, paper, etc. The *Evening Telegraph* of August 8 contains the following notice in reference to the matter: "Dr. Updegrove, who made a post-mortem examination of the body, testified that the appearances were of a negative character, as usual in cases of narcotic poisoning. The lungs were congested, and in the stomach was found an undissolved powder. Verdict, suicide by narcotic poisoning." Now, we are free to confess that we are far from being satisfied with this verdict, *based upon the above evidence*. If the paragraph from the *Telegraph* fully expresses the character of the post-mortem examination, we do not hesitate to condemn it as altogether imperfect and inconclusive. We hope, for decency's sake, as well as for that of justice and humanity, that the coroner's physician has been incorrectly reported. Surely, in a case of suspected narcotic poisoning the *brain* ought not to be omitted; yet nothing whatever is stated in reference to this all-important organ. The only pathological condition mentioned is congestion of the lungs. Now, this lesion may or may not accompany poisoning from morphia,—the alleged cause of the death; but assuredly no one is authorized to draw any positive inference from it. But the most curious point about the matter is the statement that "in the stomach was found an undissolved powder;" and then follows the verdict of the erudite jury,—"*suicide by narcotic poisoning*!"

We do not wish to be hypercritical, but, as we must presume that the "undissolved powder" was believed to be some salt of morphia (since it was termed a *narcotic* poison), we confess to being unable to perceive the logic of the conclusion arrived at. For, if we remember our chemistry aright, the salts of morphia are *soluble*, and would not be found after death in the stomach in the form of "an insoluble powder;" and, secondly, any medical man undertaking the very responsible office of determining the cause of death in a medico-legal case, and presuming to form any opinion under the circumstances without a thorough and exhaustive chemical analysis of what is simply described as "an insoluble powder," is guilty, to say the least, of gross carelessness, and of what in some countries would be called *criminal* recklessness.

We use strong language, but we speak advisedly

on this subject. It is our duty to hold up to deserved reprobation this system of loose and careless medico-legal examination, examples of which are continually presenting themselves before the public. Once satisfy a coroner's jury that the person is really dead, and the ascertaining of the true *cause* of the death is often a mere farce. An "undissolved powder" will unravel the mystery before one jury, while a simple "inspection of the stomach," as in the Delaware case, will enable another jury to determine the still more intricate question of homicide or suicide without the necessity of a trial!

CORRESPONDENCE.

THE UNIVERSITY AND HOSPITALS OF BERLIN.

TO THE EDITOR OF THE PHILADELPHIA MEDICAL TIMES:

AS a medical centre, Berlin has held a very high position for many years. Within the last decade, however, as the city has rapidly increased in population and commercial prosperity, the government has, with its accustomed beneficence to public institutions, spared no expense or effort to make this the great intellectual centre of the nation, as Vienna is of Austria, and Paris of France. A new impetus has been given to every department of the university. Distinguished men in all departments of science and literature have been called from every section of the country to fill the chairs, until the corps of instructors now numbers nearly one hundred and fifty professors and associated teachers.

The university building, a very extensive edifice, is situated in the heart of the city, and upon its principal thoroughfare, the "Unter den Linden," on which are also the palaces of the emperor and royal family, nearly opposite.

Here are delivered the greater portion of lectures, on which about two thousand students are in attendance. As many as three thousand have matriculated here in one semester; but, owing to the high prices of living since the Franco-Prussian war, the number has very much diminished. As might be supposed, the majority of the medical lectures are delivered elsewhere, principally in the hospitals.

The course of medical instruction here, and in all the German universities, is very clearly fixed. Each student desiring to pursue the regular routine of studies must present testimonials of having passed the examinations of the gymnasium, which corresponds to our colleges. The course of instruction there is nearly the same as that in our schools, rather more attention being paid to the languages, and not so much to mathematics and the natural sciences. Having matriculated in the university, he spends the first two years in the study of anatomy, physiology, chemistry, and *materia medica*. Opportunities are always afforded for practical working

in the chemical laboratory, but an attendance upon lectures is all that is absolutely required.

At the end of two years the student presents himself for examination upon the above branches, after which he is first known as a candidate for the degree of doctor of medicine. Not until then is he permitted to attend the clinics. Subsequently his course is much at his own disposal, and he can attend many or few lectures as his inclination prompts. He must, however, when he appears for examination at the end of the fourth year, show that he has attended lectures for eight semesters, and that for three semesters he has attended the various clinics.

There are some students with more money than brains, and more brains than they care to use,—more fond of the "kneipe" than of the clinic, and of the rapier than of the scalpel, preferring to pay homage to Bacchus rather than to Æsculapius,—who spend six, eight, and even ten years in some cases in the university before they appear for examination.

After the student has received the degree of doctor of medicine, he must then present himself for what is known as the "Statis examination" before he can receive license to practise. This examination is always necessary. A candidate may present himself for the Statis examination without having previously received the degree of doctor, and if his examination be satisfactory he may receive license to practise.

The principal hospitals here frequented by students are the Charité, the old municipal hospital, containing fifteen hundred beds, and the "Königliche Klinikum der Universität," containing about one hundred and five beds. The latter was intended originally to subserve a more simple purpose, as the name would indicate. Here are received only purely surgical cases, and none of those but the best which may serve for purposes of class-instruction, all others being sent to the Charité. There are also the Augusta and the Bethanien, containing respectively one hundred and two hundred and fifty beds,—both modern structures, and admirably arranged, but not visited by students, owing to their great distance from the university. Besides these, there is also the "Neue Allgem. Stadt Krankenhaus," or New Municipal Hospital, which is just completed, but not yet occupied.

A very great effort has been made to secure the most approved plans in the construction of the Bethanien and Augusta Hospitals. In the New Municipal Hospital the effort has been made to combine every improvement which experience has pronounced valuable, and the city has expended on its construction alone over one million dollars. The plan has been adopted of having a number of separate buildings at considerable distances from one another. Of these there are fourteen in all; twelve being designed exclusively for the use of patients,—six for those suffering from internal diseases, four for surgical cases, and two for contagious diseases.

The great fault connected with the management of this hospital is a law by the city authorities prohibiting

the use of the material found in its wards for the instruction of students. The great body of charity patients who now find a home in the Charité will naturally seek a place in an institution where they will not be exposed to the gaze of students and to that mystical scientific barbarity which is always supposed, by the ignorant, to be attendant upon hospital medical instruction. The Charité itself must thus lose in interest, if it be not entirely supplanted by such a rival, and medical students will find a more congenial field for study in other cities, whose authorities recognize and acknowledge the claims of science upon their hospitals.

Four-fifths of all the hospital instruction received by students here is given in the Charité.

Prof. Martin, in whose lectures I am especially interested, holds a high rank here as an obstetrician and gynæcologist. He superintends the gynæcological department of the Charité, and also has entire control of the "Königl. Entbindungs Institut," or obstetrical department of the university. During the past week he has performed the operation of ovariectomy four times, making in all eight operations of this nature during the semester. Of his manner of performing the operation, and his general success, I may have occasion to speak another time.

G. WILDS LINN.

BERLIN, July 30, 1874.

REVIEWS AND BOOK NOTICES.

A PRACTICAL TREATISE ON THE SURGICAL DISEASES OF THE GENITO-URINARY ORGANS, INCLUDING SYPHILIS. By W. H. VAN BUREN, A.M., M.D., and E. L. KEYES, A.M., M.D. New York, D. Appleton & Co., 1874.

This handsome volume is an outgrowth of the later phase of teaching, in which each of the subdivisions of medicine has a separate exponent. It is doubtless a fair expression of what is taught of the above-named subjects at the Bellevue College; and a careful perusal has convinced us that they are taught well. We have rarely read better descriptions, or more detailed yet explicit directions for treating urethral stricture and all diseases pertaining to the bladder and associated parts. We have the judgment of the expert evident on every page. The anxiety to have each department well represented is shown in the chapters on the syphilitic diseases of the eye and ear, which have been written by well-known authorities on the affections of these organs. We cordially welcome the book, and trust and believe it will meet with success.

But we cannot resist the conclusion that a mistake has been made in including syphilis in a volume treating of diseases of the genito-urinary tract. We are informed in the preface that the book has been prepared because special subjects are either omitted or slurred over in the general text-books. Yet here, within a space of six hundred and sixty-six pages, four hundred and seventy-two are devoted to diseases of the genito-urinary system, leaving two hundred and ninety-four for the consideration of syphilis. For our part, we would rather have had the proportion reversed; or, what would have been still better in our judgment, the scope of labor enlarged, and a separate volume devoted to each subject. Apart from the meagreness with which many subjects pertaining to syphilis have been treated, such, for example, as

the specific lesions of the nervous system, and hereditary syphilis, to say nothing of the provokingly elementary accounts of the syphiloderms as compared with the elaboration of the most insignificant affections of the penis, we object to the association on general grounds. What is it, we ask, that unites syphilis and diseases of the genito-urinary system? Nothing but the fact that the majority of primary sores are to be studied on the external genitals,—a fact not of first importance, compared to the fact of inoculation. The syphilographer is indifferent whether the chancre has appeared on the genitals or any other part of the body; and in questions of hereditary syphilis, and in transmission of secondary syphilis, the study of the primary lesion is of no value whatever. Nor do we understand why such remote subjects as urethral stricture or spermatorrhœa, and constitutional syphilis, should be treated together in a special text-book, unless, indeed, it be out of respect to certain rather ancient ideas,—ideas to which our authors have in no way committed themselves.

It is to be hoped that a certain carelessness in diction which mars portions of the book may be corrected in future editions. Our authors speak of a "type case" of atrophy of the bladder; of the "cut-off" muscles of the urethra; of involuntary ejaculations during sleep being nature's safety-valve (!); of a lymphatic (?) young man virgin (!!); of all antecedent venereal disease; and of inflammation of the glands of Cowper as *Cowperitis*. We are told that the bladder is "almost invariably unique," that "lithotomy is respectable for its longevity," that the "prognosis of tubercular prostatitis is bad," that "a catheter passed into the bladder insures the right of way to the urine."

Such inaccurate and inelegant expressions are, unfortunately, heard too often in the amphitheatre, but are, to say the least of it, out of place in a text-book. H. A.

LES NEUROSES MENSTRUÉLLES. Par le DOCTEUR BERTHIER. Paris, A. de la Haye, 1874.

We have perused with some interest this treatise, which is, in fact, a compilation and comparison of cases recorded in medical literature already, with such comments upon them as to show their connection with and relation to excess, suppression, or irregularity of the menstrual flux. To these are added the views of the author on the physiology of the secretion and its intimate association with the condition of the nervous system, and on the subject of sympathy and reflex phenomena,—views which are correct so far as they go, but seem to us more like mere truisms than a statement of the actual status of our knowledge in this latter half of the nineteenth century. Perhaps they are necessary in the atmosphere of Paris, where the anatomico-physical school of thought has almost stifled the vitalist doctrines of Montpellier. "Truth crushed to earth will rise again," and from time to time there come to us utterances from Paris itself pointing to a consciousness on the part of the leaders of medical thought in that Vanity Fair that even in such apparently capricious things as congestions there is a force, an archæus, that obeys laws other than those of ordinary physics. To us in this country who have been taught to recognize this *vis insita*, there is much that seems like groping in the dark, and many "most lame and impotent conclusions" from facts such as those recorded in the present volume. And yet it is precisely such testimony that we need, coming from an entirely different point of view, to confirm our faith, which might otherwise be rudely jostled, not to say severely shaken, by the demonstration on the part of the physical-theory advocates of how many apparently pure mental phenomena are after all the result of purely physico-mechanical conditions. The cases cited by Berthier are not generally rare ones; there is hardly any practitioner of large

experience who will not be able to call to mind some similar ones which he has witnessed and perhaps not thought it worth while to record even in his private note-book. And yet, when they are thus arranged in proper sequence, we see how they prove by cumulative argument overwhelming in force the truth and importance of the influence reciprocally of the nervous system and the generative system upon each other. Nervous irritability and the "irritable uterus" are things which we would gladly consign to the limbo of the past; but, like Banquo's ghost, they will rise and confront us in the midst of our medical "feast of reason." Nor will they be laid until we learn that perverted, suppressed, or excessive function will and must lead first to functional, then to organic, disease; and that not only of the organ which is thus subjected to unhealthy influences, but of one or all of the others which are allied to it by those subtle, impalpable, and yet undeniable influences which we call "sympathies." Our medical predecessors, with their far inferior means of physical diagnoses, relied more upon these sympathies for their diagnosis and indications for treatment than we do, and mastered their meanings in a mode which is for many of us a "lost art." Which one of us is not rather disposed, for instance, to think of the tongue as deceitful above all things, in comparison with the means of information afforded by auscultation and percussion, by the thermometer and the ophthalmoscope? And yet our predecessors were grand old practitioners, and accomplished in their day cures as wonderful as some of those we boast of. If we look into their writings with the light of modern science to help us to understand clearly difficulties among which they groped darkly, we shall rise with a profound respect for the acumen which they display, and also with the feeling that there are many of those things in the science of medicine which our philosophy scarce dreams of as yet, in the solution of which we may gain much assistance, as they did, from the patient, laborious investigation of symptoms which now, unless we can correct them with or explain them by our present theories, we are too apt to ignore.

One other thought has suggested itself to us in perusing this volume. If nearly one-fourth of the life of women between fifteen and forty-five years of age is passed, as we know, in a condition which renders them liable to severe nervous disturbance, and if one woman out of every five (we fear an accurate statistical statement would make these figures nearer to two out of three) actually experiences such perturbation in her organism as to affect her power of active exertion, of untrammelled thought, of calm judgment in a greater or less degree, is there not in these facts the most convincing argument against the adaptedness of women as women for the exercise of such professions as, like our own, demand coolness, clearness of head, steadiness of hand and eye, and, above all, that all the faculties shall always be ready, at an instant's warning, for their fullest exercise? In other professions arrangements might be made to obviate the regular recurrence of the greater or less disability entailed by the menstrual epochs, but in ours it seems an obstacle that, lying in the nature of things as regards the woman of our day, is not likely to be overcome. J. C. M.

THE PHYSIOLOGY OF THE CIRCULATION IN PLANTS, IN THE LOWER ANIMALS, AND IN MAN. By J. BELL PETTIGREW, M.D., etc. London, Macmillan & Co., 1874.

The author's design in the arrangement of the contents of this volume is "to give a comprehensive account of the circulation and the apparatus by which it is effected in plants and animals." Judged by this standard, the book is disappointing. The descriptions

of the circulation in plants are faulty and incomplete, and those of the lower animals are mere fragments, of no value whatever. The most elaborate work is devoted to the circulation of the vertebrata; and one may infer how far the author aids the student who reviews his "comprehensive account," when the batrachian and reptilian types of life are confounded.

The book will doubtless prove suggestive to the special student of physiology, who will be pleased with the author's observations on the heart's action, while he will justly esteem the chapter on the fetal circulation, the mechanism of the valves of the vascular system, and the ganglia and nerves of the heart, as elaborate essays, valuable for reference.

The motive in publishing such a collection of a lecturer's memoranda has not been vouchsafed us by the author, nor do we profess to be familiar with the points of the canvass now pending for the chair of physiology in the University of Edinburgh. H. A.

THE PHYSIOLOGY OF MAN. By AUSTIN FLINT, Jr. Vol. V. New York, D. Appleton & Co.

This volume, embracing the subjects of the special senses and generation, completes the great work of Prof. Flint, and we congratulate him upon the completion of his task, and upon having added to American literature the most thorough and complete work on physiology in the English language. The preceding portions of this work have been noticed in this journal from time to time, as they appeared, and it seems scarcely necessary to present a detailed review of the present volume, in which the general tone and style of the previous volumes of the work are well maintained. The completed work of Prof. Flint is too large for use as a text-book, but is par excellence the book for those practitioners who wish to keep themselves upon the level of the day in regard to the great sciences which underlie the practice of medicine.

GLEANINGS FROM OUR EXCHANGES.

PERCHLORIDE OF IRON IN POST-PARTUM HEMORRHAGE.—Dr. Lombe Atthill, in a paper read before the Dublin Obstetrical Society, states that he has arrived at the following conclusions:

1. That cases of post-partum hemorrhage occur in which the injection of the perchloride of iron or some similar styptic is alone capable of arresting the hemorrhage.
2. That the injection of such styptic does not necessarily increase the tendency which exists in such cases to the occurrence of pyæmia, septicæmia, or peritonitis.
3. That this treatment is specially applicable to anæmic patients.
4. That while it should never be had recourse to unnecessarily, it should not, on the other hand, be delayed too long.

ANEURISM OF THE LEFT SUBCLAVIAN ARTERY CURED BY DISTAL LIGATION (*The Western Lancet*, July, 1874).—In a case of subclavian aneurism of a year's standing, attended with partial paralysis of the left arm from pressure on the brachial plexus and great anæmia due to pressure on the thoracic duct, Professor Toland decided to perform the distal operation, and the artery was tied at its exit from the axilla. The pulsation in the tumor was immediately lessened, and gradually decreased up to the sixth week from the date of the operation, after which no bruit or pulsation could be discovered. The tumor grew smaller, the collateral circulation became fully established, the paralysis almost entirely disappeared, and the patient gained considerably in weight.

AMYLOID AND FATTY LIVER IN RELATION TO OPERATIONS (*The Lancet*, August 8, 1874).—Mr. Richard Barwell details two cases of hip-disease in children, which had been attended with prolonged suppuration, and in both of which a cachectic condition had ensued, attended with extreme enlargement of the liver. Operations for the relief of the joint-trouble—in the one case amputation at the hip, in the other excision of necrosed bone—were both followed by great improvement and subsequent recovery, *with a gradual return of the liver to its normal size.*

We often see in such cases as these, where free suppuration has existed for a long period, a uniform increase in the size of the liver, which does not affect by pressure or obstruction the portal circulation, since it is not accompanied by ascites; and, though it may diminish, it does not annihilate the secreting function of the gland, since the fæces are colored with bile, and since there is no jaundice.

This enlargement is due to the deposition in the constituents of the organ either of oil-globules (the fatty liver), or of a material called amylaceous (the amyloid or lardaceous liver).

Now, in healthy life fat is frequently present in and is often removed from the liver. It is therefore plain that recovery from its morbid accumulation in that organ is a much more easy process, a far more likely event, than restoration to the normal condition of a liver infiltrated with so immobile a material as that which constitutes the amyloid deposit.

Amyloid liver may be suspected if the organ attains a very large size, if there be obstinate and recurrent diarrhœa, with cast-off villi in the excreta but no pus or sign of ulceration, or if there be albumen in the urine.

If, after careful investigation on these points, the absence of any sign of amyloid disease save the enlargement of the liver be determined, any operation for the removal of suppuration is not only justifiable, but our imperative duty. Without operation the patient must die; after operation, however hard, large, and changed be the liver, there is a fair, indeed a considerable, chance of recovery.

Mr. Barwell believes that in both his cases there existed amyloid disease of the liver, although he admits that he is unable to prove absolutely his position, and that the whole balance of opinion is that amyloid disease once commenced is of necessity a progressive and fatal malady.

RABIES MEPHITICA.—Rev. Horace C. Hovey, of Kansas City, Mo., writes to the *American Journal of Science and Arts* concerning a fatal disease which is communicated by the bite of the skunk, and which bears certain resemblances to hydrophobia. The rabid skunk seems to have exhausted his mephitic battery, or else has lost the projectile force by which it is discharged. Perhaps the secretion has been checked by the feverish state of the system; or there may be a causative connection between the inactivity of the anal glands and the generation of malignant virus in the glands of the mouth.

The writer, having had his attention called to the disease by an encounter with a skunk, and by the statement of an experienced hunter that the bite of the animal is invariably fatal, opened a correspondence with hunters, taxidermists, surgeons, and others, and obtained the particulars of forty-one cases of *rabies mephitica* occurring in the Western and Southern States. All were fatal except one. Drs. Janeway and Shearer, Surgeons U.S. Army, reported several cases which resulted fatally from the bite of the skunk. Dr. Shearer wrote that he regarded the virus as peculiar to the skunk, as the venom of the rattlesnake is to that

creature, and not an occasional outbreak, as in the case of the wolf or the *rabies canina*. From this opinion, however, Mr. Hovey dissents.

The attack of the rabid skunk is entirely different from the fierce assault of a mad dog. He approaches stealthily while his victim is asleep, and inflicts a deadly wound on some minor member,—the thumb, the little finger, the lobe of the ear, one of the alæ of the nose.

The resulting disease resembles hydrophobia more than it does the effects of ophidian venom. The period of incubation is alike in *R. canina* and *R. mephitica*. It is indefinite, ranging from ten days to twelve months. During the incubative stage, no perceptible change takes place in the circulation.

The spasms of the larynx and œsophagus which occur in *R. canina* are wanting in *R. mephitica*. Nor is the hyperæsthesia of the skin which is so marked in the former disease present in the latter. In hydrophobia the perceptions are intensified, but in mephitic rabies there is a positive loss of perception and volition.

The mode of death is by anæsthesia in both forms of rabies; but in that of the dog the frightful struggles of nature to eliminate the poison are more prolonged than in that of the skunk.—*Boston Medical and Surgical Journal.*

THE ACTION OF STIMULANTS (*The Practitioner*, August, 1874).—Dr. James Ross defines stimulants to be "those agents which determine the living tissues to energize, no matter what the form of evolved energy may be, whether it be heat, electricity, secretion, growth, nerve-force, or contraction." Careful observation shows that by far the greater number of the agents used as medicines act by first stimulating one or other of the tissues of the body to expend energy in some form; and when this action is continued, the second effect is to incapacitate the tissue for further action. The maxim, however, that effects are proportional to their causes is frequently and wrongly assumed to be applicable to stimulants and their effects. We ought to be extremely careful in inferring that because a certain dose of a medicine produces a particular action, an increase or decrease of the dose will produce corresponding variations of the effect. In the experiments of the Edinburgh Committee on the action of mercury it was assumed that because a large quantity of the drug diminished, or did not increase, the quantity of bile, *a fortiori* a small dose cannot augment its flow. The inferences from these experiments are vitiated by the neglect of the relation which subsists between the primary and secondary action of a drug and the opposite effects produced by large and small doses. The facts that a strong dose of curara destroys the irritability of the motor nerves while a feeble dose increases it, that a strong dose of alcohol stupefies the brain while a small dose excites it, and that this relation is found to exist between large and small doses of stimulants of all orders, afford good presumptive evidence that since large doses of mercury diminish the biliary secretion, small doses will be found to increase its flow.

TUBERCULAR SPINAL MENINGITIS WITH DEPOSIT OF TUBERCLE IN THE LIVER AND PERITONEUM (*The Indian Medical Gazette*, July 1, 1874).—Surgeon-Major J. Wise reports a case of tubercular deposit in the meninges of the cord, attended by choreic disturbances, great hyperæsthesia of the surface, active delirium, paralysis of the legs, peritonitis, and a fever, which at first assumed a regular remittent, and then an intermittent, form.

At the autopsy, in addition to the tubercles found in the spinal membranes, the capsule of the liver was found to be studded with them, and the whole of the peritoneal covering of the bowels was infiltrated with hard miliary tubercles.

THE INDUCTION OF PREMATURE LABOR (*British Medical Journal*, August 8, 1874).—Dr. J. G. Swayne reports twenty cases of the induction of premature labor, and describes the method which he prefers, as follows. The patient being in the ordinary obstetric position, the fore and middle fingers of the left hand, well oiled, are to be passed up to the os uteri externum, which is generally sufficiently open to admit the point of one, and sometimes even of both, fingers. A small-sized sponge-tent, about the size, for instance, of an ordinary radish, is to be mounted on a proper stilette, made for the purpose, and passed along the groove between the fore and middle fingers of the left hand, until its point is inserted into the os uteri. The tent is then to be pushed on until a very little of it, not more, perhaps, than a quarter of an inch, projects into the vagina beyond the os uteri. If the os be so high that it cannot well be reached by the finger, the tent may be inserted through a full-sized tube speculum. If also it be very little open, a tangle-tent may be found more convenient to begin with. Care should be taken to push the tent up sufficiently far, as it should be remembered that, two months or so before delivery, there is often a considerable interval between the os uteri externum and internum; otherwise the tent may not pass through the os internum. After the tent is introduced, a piece of soft silk handkerchief may be passed up as a plug to keep it *in situ*. On the day following, this tent should be removed, and a large one inserted, and, on the next day, a tent of the largest size. Generally two, or at most three, tents are required to complete the full dilatation. At this time, probably, labor-pains will set in regularly, and the membranes will rupture. Should this not be the case, the membranes may be punctured, and the most convenient instrument for this purpose is a gum elastic male catheter, of which the end has been cut off, so that the stilette can be protruded at pleasure. Should the pains still be weak or ineffectual, ergot may be given.

The tents employed should be impregnated with carbolic acid.

DIAGNOSTIC POINTS IN CEREBRAL DISEASE (*Buffalo Medical and Surgical Journal*, June, 1874).—From recent investigations into the physiological functions of the brain, Dr. H. R. Bigelow concludes—

1. That grave cerebral lesions may exist without characteristic semeiology.
2. That slight lesions may occasion a train of symptoms indicative of serious organic disease.
3. That a paralysis is caused by the irritation transmitted by the cerebral lesion, inhibiting certain functional actions, and not by the mere circumscribed pressure.
4. That a lesion in the middle line, *i.e.*, affecting both sides of the optic thalami, corpora striata, etc., may produce paralysis of but one side of the body.
5. That a paralysis may exist on the same side with the lesion.
6. That unilateral convulsions are much oftener associated with lesion of the right brain than with lesion of the left.
7. That hysterical paralysis, etc., depends oftenest upon disorganized action of the right brain.
8. That aphasia, agraphia, a mechanical impairment of speech, and mental alienation, are usually associated with disease of the left brain.
9. That the right brain is more capable than the left of producing a paralysis on the same or on the opposite side of the body.
10. Optic neuritis as a cause of amaurosis depends more often on a disease of the right brain than on disease of the left.
11. The symptoms may indicate a double lesion when one is present, and conversely.

POPLITEAL ANEURISM (*British Medical Journal*, August 8, 1874).—Professor Holmes has come to the following conclusions in reference to the treatment of popliteal aneurisms:

1. Rapidly-growing aneurisms, with a thin or imperfect sac, are best treated by immediate ligature, especially when caused by recent violence; and the success of compression is doubtful in aneurisms growing towards the knee-joint, and in all others which advance rapidly.
2. The Hunterian ligature has been about twice as successful in modern hospital practice as the results of the accepted statistics show it to have been.
3. The results of the compression-treatment have given as yet about the same average results as those of the ligature; but these results might be much improved by a more careful employment of the method.
4. Too long persistence in compression is to be deprecated, as being likely to interfere with the success of the ligature.
5. Flexion is often successful when used so as not to distress the patient, and is worthy of a trial in all cases in which it stops or materially checks the pulsation, but should not be long persisted in when it is not at once beneficial.
6. We have no evidence showing the utility of or the need for the less usual forms of treatment, such as galvanism, coagulating injections, manipulation, temporary ligature, or the introduction of foreign bodies.

UTERINE FIBROID TREATED HYPODERMICALLY BY ERGOTIN (*The American Practitioner*, August, 1874).—Dr. George Cowan reports the case of a woman, *æt.* 40, who presented herself for treatment of a fibroid tumor of the uterus, which had originated eight years previous. There were obstinate constipation, uterine tenesmus, swelling of the feet, and pains and numbness in the right leg and side. At the most prominent point of the abdomen she measured thirty-six inches in circumference. The abdominal walls were smooth and shining, and seemed stretched to their utmost. For two weeks one and a half to two grains of ergotin in twenty minims of distilled water were injected daily into the subcutaneous tissue of the abdomen, with the following results: the greatest circumference was reduced to twenty-eight and a half inches; the bowels had acted daily for several days, freely and without the use of medicine; the abdominal walls were greatly relaxed; the presence of several tumors instead of a single one was detected; and the patient much improved in health, strength, and spirits. The treatment being interrupted, she returned to her former condition, but on recommencing the injections she again greatly improved, and is now relieved of nearly all the most distressing symptoms.

Dr. T. Parvin records (*American Practitioner*, May, 1874) three cases of uterine fibroid in which marked benefit followed the use of this method. Dr. A. Reeves Jackson reported to the Chicago Society of Physicians and Surgeons (*Chicago Medical Journal*, June, 1874) five cases, in three of which the results were decidedly favorable. Five other cases were reported at the same time, in all of which the results had been beneficial.

CHLORALUM IN CHOLERA.—The internal use of chloralum in cholera is highly recommended by Dr. Henry Blanc, surgeon in the Indian army. His mode of administration was, one part of liquid chloralum to twenty-five parts of water, an ounce of the mixture to be given every half-hour; also an enema containing sixteen ounces of the mixture to be administered every hour. Undiluted chloralum sprinkled on and around the bed. Remedy given less frequently as the reaction became more completely established.—*St. Louis Med. and Surg. Jour.*, July, 1874.

TWO CASES OF SPONTANEOUS RUPTURE OF THE UTERUS (*New York Medical Journal*, August, 1874).—Dr. W. T. Lusk records the case of a woman, æt. 32, in her tenth pregnancy, who was taken with labor-pains about the middle of the day. At 7.30 P.M. a breech-presentation was recognized; at 11.30 P.M. the membranes broke; at 3 o'clock sudden collapse occurred, the pulse was hardly perceptible, the breathing hurried, and the extremities cold. She complained of pain in the right hypochondriac region, and of intense thirst. At 3.30 a dead child, weighing ten pounds eight ounces, was extracted. The woman never rallied, and died at 7 o'clock. At the autopsy, a laceration involving both the peritoneum and muscular structures was found crossing the middle of the cervix and stretching up in the right side so as to involve a portion of the body. No thinning or abnormal condition of the uterine tissues was noticeable.

In another case, a woman, æt. 38, was pregnant for the sixth time, and when she came under observation the membranes had broken, the labor-pains had ceased, and she was in an advanced stage of collapse from hemorrhage. A male child much decomposed was delivered, and the patient died with symptoms of shock. The autopsy revealed a large laceration communicating with the peritoneal cavity, and extending across the posterior surface of the uterus just above the cervix. A smaller laceration was found in the anterior surface, not extending through the peritoneum, but lifting it up so as to form an enormous thrombus.

MISCELLANY.

HYDROPHOBIA AFTER AN INCUBATION OF THIRTY MONTHS.—A medical man recently died in the Paris Maison Municipale de Santé (a valuable institution, being a well-appointed hospital for patients able to pay the charges, which vary according to the accommodation), of the most undoubted symptoms of rabies. Dr. Féréol, who had the management of the case, gives the following summary. An individual enjoying perfect health, temperate in his habits, and with no hereditary propensity to insanity, is seized, after laboring under low spirits for a few days, with fits of rabies, which carry him off in three days. On a post-mortem examination the lesions usually observed in cases of hydrophobia were found. Two years and a half before the outset of the fearful disease which destroyed him in so short a time, the patient had been bitten by a bitch which was in a rabid state. The animal was examined after death by a veterinary surgeon, who certified to the existence of rabies. It should, moreover, be observed that the bitch, at the time she became rabid, was suckling a pup, which died hydrophobic three weeks after the mother.

M. Féréol, under whose care the patient died, has sent an elaborate essay to the Academy of Medicine on the case. A lively and instructive discussion is expected. The essay concludes with the following deductions. 1. The incubation of rabies, which is mostly limited within the first two months after inoculation, may exceptionally last much longer, and may reach eighteen months, or even two years and a half. 2. The symptoms of the disease are generally of a uniform description, but they may assume various aspects under the

influence of numerous agents; as insanity, alcoholism, hysteria, etc. There are, however, certain signs, such as spasm of the glottis, a peculiar mode of sputation, and the symptom known under the name of aerophobia, which belong especially to rabies, and which allow of the diagnosis of the disease, although accompanied by the above-named complications. 3. Idiopathic or imaginary rabies, which is not generally fatal, may end in death: in such case the symptoms will yield sufficient reasons for holding that actual rabies did not exist. 4. The bronchial spuma with rabid patients plays an important part in the phenomenon of sputation, and it may be safely affirmed that the principal symptoms as well as the principal lesions of rabies, in the human subject, are concentrated upon the function of respiration. The characters of the breathing distinguish rabid hydrophobia from the cases of hydrophobia depending on a non-virulent cause.—*London Lancet*.

"CAN ANY GOOD THING COME OUT OF NAZARETH?—I, of course, in common with all sensible people, have long since abandoned the idea that the ablest medical men are always to be found in the largest medical centres; for the history of this country, with that of all other countries, shows that very often the men who give to medical science its greatest improvements—whose genius is so great as to be impressed upon the medical history of the times—come from rural hamlets and small country towns. Velpeau, Magendie, Trouseau, Sir William Gull, Sir James Simpson, Sir Henry Thompson, in Europe; Warren Stone, Eve, Dudley, McDowell, Gross, Sims, and a host of others, in this country, all in their lives illustrate this fact."—*New York Correspondent American Medical Weekly*.

This is undoubtedly true; but it is no less true that these great men, with rare exceptions, sooner or later settle in the medical centres.

ONE of the religious sect known as "The Peculiar People," who object to calling in a physician on account of its showing a lack of faith in God, was recently held in England for trial on the charge of manslaughter. His child had died of pleuritis and pericarditis without professional attendance.

ACCORDING to the statements of the *London Lancet*, Sir William Thompson must be already *en route* for this country.

M. CULLERIER, the Parisian syphilographer, died August 3.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY, FROM AUGUST 25 TO AUGUST 31, 1874, INCLUSIVE.

SMITH, A. K., SURGEON.—Granted leave of absence for thirty days, on Surgeon's Certificate of Disability. S. O. 135, Department of the Missouri, August 26, 1874.

WRIGHT, J. P., SURGEON.—Relieved from duty at Fort Hays, Kansas, and assigned to duty as Chief Medical Officer, District of New Mexico, Santa Fe, New Mexico. S. O. 132.

SATURDAY, SEPTEMBER 12, 1874.

ORIGINAL COMMUNICATIONS.

AN INVESTIGATION INTO THE ACTION OF VERATRUM VIRIDE UPON THE CIRCULATION.

BY H. C. WOOD, JR., M.D., ASSISTED BY JOS. BERENS, M.D.

(Concluded from page 771.)

PART II.—VIRIDIA.

Section A.—Action on the Circulation.

MR. MITCHELL announced some time since that he had found jervia in the root of veratrum viride. In a more recent, and as yet unpublished, investigation, he failed to get what he was looking for,—the viridia of Bullock,—and was finally forced to conclude that his jervia was the same as the viridia of Bullock. After he had placed some of his jervia in my hands, my first experiments were directed to discovering whether this conclusion was true. Without giving these experiments in detail, it is allowable to state that the symptoms induced by his jervia were precisely those which I had seen caused by viridia. The same general quietness and weakness, the same peculiar trembling or muscular thrill ending in general convulsions, the same free salivation and absence of vomiting and of purging, were present in either case. In elaborate cardiometrical experiments the two alkaloids have also given identical results. I have no hesitation in asserting that they are one. As to the reason or cause of the asserted chemical differences I will not at present offer an opinion, but leave the Messrs. Bullock and Mitchell to settle it between them.

The general effect of viridia upon the circulation is well portrayed in the following experiments, which have been already published with more detail in the *American Journal of the Medical Sciences* for January, 1870.

Experiment XXXIII.—A moderate-sized cur.

TIME.	DOSE.	PULSE.	PRESSURE.	REMARKS.
0	m.		120-160	Viridia injected into thigh.
5	"	gr. ½	120-160	
15	"		120 (maximum.)	
20	"		65-95	Dog quiet. Injected into peritoneal cavity. Convulsions. Dog quiet.
30	"	gr. ½	65-75	
40	"			
45	"		125	
50	"		75	

Experiment XXXIV.—A stout Scotch terrier.

TIME.	DOSE.	PULSE.	PRESSURE.	REMARKS.
0	m.	gr. 1½	186	Hypodermically.
5	"		120-130	
10	"		115-125	
15	"		160	Dog quiet.
20	"		110-120	
25	"		128	
30	"		80	
35	"		85-105	

These two experiments show that when viridia in suitable amount is given to a dog, the pulse as well as the blood-pressure falls very decidedly, without the production of marked symptoms other than general weakness. In order to confirm this, and at the same time to corroborate the opinion already expressed, that jervia and viridia are one thing, the following experiment was performed with some jervia obtained from Mr. Mitchell:

Experiment XXXV.—A stout slut.

TIME.	DOSE.	PULSE.	PRESSURE.	REMARKS.
0	m.	135	105-120	Injections into the femoral vein. The jervia very impure.
2	"	132	105-120	
2½	"	gr. 1-20		Dog breathing heavily. Doubtful how much went in.
4½	"	128	95-100	
6½	"	112	95-100	
7½	"	52	30-65	
8½	"	76		
9½	"	83	85-90	
10	"		95-105	
12	"	88	90-100	
15	"	112	100-110	
15¾	"	gr. ½		
19	"	90	70-75	Dog very quiet.
21	"	92	65-70	
22½	"	96	90-95	
24	"	92		
27	"	gr. 1-20	100-105	
28	"	72		
30	"	48	45-60	Dog quiet.
34	"		70-80	
35	"		75-85	
36	"			
47½	"		85-90	Clot. When dog struggles, pressure rises to 100. Began to fall almost instantly.
48½	"	gr. 1-12		
49	"	84	50-60	
49½	"		55-65	
50½	"		70-75	The dog has been struggling, to which the rise in pressure is probably due. Respiration is affected, but only in small degree.
55	"	gr. 1-12	85-90	
58	"	gr. ¼		Clot. Most violent, persistent convulsions have come on. The limbs shaking violently, all the muscles rigidly contracted. This, together with the violent respiratory efforts, drove the mercury up to 140, and even momentarily to 180.
66	"		100	
73	"		60-75	Tube has been placed in carotid. The dog momentarily quiet. Convulsions have again set in. There is no perceptible cardiac impulse.
74	"		110-125	
76	"	gr. ¼	85	Dog still convulsed.
78	"		90	
81	"		75-85	
83	"		75-80	
				Clot. Respiration ceased. Heart found to be still pulsating; this continued for some time after entire arrest of respiration.

In comparing this experiment with those previously published, it must be borne in mind that in the last experiment the poison was thrown directly into the veins, and that therefore much more intense and especially more sudden effects are to be looked for; it should also be remembered that it is probable the specimens furnished by the Messrs. Bullock and by Mr. Mitchell were not of equal purity. Due allowance being made for these disturbing causes, I do not see how a close study of the records can fail to reveal the identity of the two alkaloids. The great rise of

pressure during the later periods of the last experiment was certainly owing entirely to the convulsions, the mercury in the cardiometer falling so soon as the muscles relaxed; the phenomenon finds its counterpart in the first experiment with viridia.

Section B.—Action on the Heart and its Nerves.

In endeavoring to discover the exact method in which viridia lowers the pulse and blood-pressure, I first investigated its action upon the cardiac inhibitory system, and made the following experiments: those marked (V.) were performed some years since with Mr. Bullock's alkaloid; the others were made with samples furnished by Mr. Mitchell.

Experiment XXXVI. (V.)—A small cur.

TIME.	DOSE.	PULSE.	PRESSURE.	REMARKS.
0 m.	gr. 1½	184	146-152	The pneumogastri- cals had been cut some time previously. Hypodermically given. Pressure during struggles vi- brates between 70 and 105. Dog struggling some.
25 "	"	72	80-90	
30 "	"	80	65-95	
45 "	"	76	50-60	
60 "	"	68	38-60	

Experiment XXXVII. (V.)—A young mongrel.

TIME.	DOSE.	PULSE.	PRESSURE.	REMARKS.
0 m.	gr. 1	176	110-120	Par vagum already cut. Given hypodermically.
5 "		"	"	
20 "		164	110-115	During struggles pressure falls to 70 and rises to 105.
30 "		80	75-95	
40 "	"	76	65-85	Constant convulsive tremors very marked; when they are especially violent the pressure rises to 110.
60 "	"	70	65-95	

These experiments are sufficient to show that the reduction of the pulse produced by viridia is entirely independent of any action upon the cardiac inhibitory nerves. In order to determine whether large doses of the alkaloid paralyze the peripheral inhibitory cardiac nerves, further studies were required.

In two experiments, detailed below, the effect of galvanism upon the par vagum was therefore studied in a dog profoundly under the influence of the drug. An examination of the record of Experiment XXXVIII. will show that after the injection of a fifth of a grain of a very pure sample of the alkaloid into the veins, the cardiac inhibitory nerves were exceedingly sensitive to stimulus, and also that this sensitiveness was very slightly diminished by the further administration of nearly a grain and a half of the poison. In Experiment XXXIX. the amounts of the poison exhibited were very much less, but, as the animal was a very young pup, the effects of these doses were very marked,—arterial pressure falling to one-half its primitive height; yet the sensitiveness of the inhibitory apparatus was preserved intact. The first of the experiments seems to show that in enormous quantity the poison does slightly lessen the sensitiveness of the par vagum, but it is very possible

that the diminution of sensibility alluded to may have been due to exposure of the nerves or some other accidental cause; at any rate, the experiments show that if viridia, even when given in enormous doses, has any action upon the cardiac inhibitory apparatus, such action is so slight that it may be practically disregarded. The experiments are as follows:

Experiment XXXVIII.—A stout dog. Spine cut.

TIME.	DOSE.	PULSE.	REMARKS.
0 m.	gr. 1-20	160	Into femoral vein.
10 "	gr. 1-10	"	Into femoral vein.
16 "	"	100	"
17 "	gr. 1-20	"	Into a vein of the neck.
19½ "	"	92	"
20 "	"	110	"
21 "	"	"	One pneumogastric cut.
24 "	"	112	"
32 "	"	108	Dog lost considerable blood.
32½ "	"	"	Cut remaining pneumogastric.
33 "	"	116	"
38 "	"	116	A moderately strong current to par vagum caused immediate diastolic arrest.
42 "	gr. 1-10	"	Into jugular vein.
43 "	"	120	"
43½ "	gr. ½	"	Into jugular vein. Immediate convulsions confined to the anterior part of the body.
47½ "	gr. ¾	"	Into carotid artery.
49 "	"	116	"
51 "	"	116	Galvanic current of the same strength as be- fore has a very decided effect on the heart, but does not completely arrest its move- ments.

Experiment XXXIX.—A small young pup. Woorari used, and spine and par vagum cut.

TIME.	DOSE.	PRESSURE.	REMARKS.
0 m.	gr. 1-10	95-105	Into peritoneal cavity. A mild current applied to par vagum caused immediate diastolic arrest.
13 "	gr. ½	"	
24 "	"	40-45	

It having been determined that neither the slowing of the pulse-rate nor the diminution of the arterial pressure produced by viridia is dependent upon an action of the poison upon the cardiac inhibitory apparatus, the question logically presents itself, whether the first of these phenomena is due to an action upon the accelerator cardiac nerves, and the second to an influence upon the vaso-motor nerves, or whether both are the result of a direct influence upon the heart-muscle.

In order to determine whether the slowing of the pulse was independent of the accelerators of the heart, in the following experiment the attempt was made to divide the spine so high up as to paralyze these nerves, and in this way to eliminate their action from the problem. Unfortunately, at the post-mortem, care was not exercised to determine the exact point at which the spine was cut, and the single experiment is open to the objection that the supposed section of the accelerators was not anatomically proven to exist. As, however, the physiological result of such division was obtained, namely, a very slow pulse, such objection is perhaps more specious than valid. The experiment is as follows:

Experiment XL.—A terrier pup. Spine cut in lower cervical region. At the autopsy one lateral column found not to be completely crushed.

TIME.	DOSE.	PULSE.	REMARKS.
0 m.		96	Artificial respiration commenced.
3 "		82	
7 "	gr. 1/6		Into femoral vein.
23 "		80	
27 "		80	
34 "	gr. 1/3		Into peritoneal cavity.
35 "		68	
44 "		50	
46 "			Par vagum cut.
52 1/2 "		48	

The record of this experiment proves that the reduction of the pulse-rate by viridia is independent of the nerve-centres. As a matter of course, when the pulse is already slowed by division of the accelerators, the fall is not so great after exhibition of the alkaloid as in the uninjured animal. Yet, in spite of the division of the par vagum, the poison reduced the pulse to nearly one-half its original rate. The experiment does not, however, warrant the further deduction that the alkaloid has no action upon the accelerators, since it is evidently possible that an influence upon the nerves and upon the heart-muscle might be exerted simultaneously. The point must be left for future investigation; but I think the present light indicates that if viridia does act at all upon the accelerators, such action must be of minor importance.

The next point which logically offered itself for determination was whether the fall of the arterial pressure produced by jervia is due solely to an influence upon the vaso-motor nerves, or whether the poison lessens the working-power of the heart-muscle. In the following experiments a study was made of the effect of the drug upon the arterial pressure after paralysis of the vaso-motor nerves by section of the cord.

Experiment XLI.—A stout dog. Cord cut in the extreme upper dorsal region at 11.15 A.M.; observations commenced 11.25 A.M.; the jervia employed containing a good deal of resin.

TIME.	DOSE.	PULSE.	PRESSURE.	REMARKS.
0 m.			90-100	Artificial respiration commenced.
1 "			80-85	
4 "	gr. 1-20	160	75-85	Into femoral vein.
5 "		135	80-90	
7 "	gr. 1-20		80-90	Into femoral vein.
8 "		140	80-90	
9 "			75-80	
10 "		120	60-70	
11 "		120	50-55	
12 "			50-60	
14 "	gr. 1-10		60-65	Into femoral.
15 "			60-65	
17 "		120	65-70	
20 "		100	55-60	There appears to be a clot in the femoral vein interfering with passage of alkaloid into the circulation.
21 "	gr. 1-20			Into vein in neck.
21 1/2 "		108	45-50	
22 "		116	50-75	
22 1/2 "	gr. 1-10			Into jugular vein.
23 "			40-45	
23 1/2 "		92	45-50	

TIME.	DOSE.	PULSE.	PRESSURE.	REMARKS.
24 m.		110	40-50	Pneumogastrics cut a few minutes since. Dog has lost some blood.
39 "		116	30-35	
42 "		116	50-55	Into jugular.
46 "	gr. 1-10		50-55	
47 "		120	50-55	Into jugular.
47 1/2 "	gr. 1/2			
48 1/2 "			45-50	Into carotid.
51 1/2 "	gr. 3/4			
52 "			35-40	
53 "		116	35-40	
55 "		116	35-45	
61 "	gr. 1/2			Into jugular. Violent convulsions at once confined to the anterior part of the body.
63 "		120	30-35	Galvanization of spine caused a general convulsion of a mild type, with a rise of the blood-current to 70 or 80, the pulse instantly becoming exceedingly rapid. On withdrawing the poles, the mercury fell at once, in half a minute standing about 40,—the pulse being 208.
65 "		112	35-40	

Experiment XLII.—A terrier pup. Cord divided in lower cervical region. At the autopsy one lateral column found not to be completely mashed.

TIME.	DOSE.	PULSE.	PRESSURE.	REMARKS.
0 m.		96	100-135	Artificial respiration resorted to at end of first minute.
2 "			95-100	
3 "		82	100-105	
7 "	gr. 1/6		115-125	Into femoral vein.
9 "				Convulsions in anterior part of the animal.
30 "			55-75	Artificial respiration very active.
34 "	gr. 1/3			Into peritoneal cavity.
35 "		68	115-125	Convulsive rigors and tremblings in anterior part of body very marked, and, to some extent, in one-half of posterior portion.
44 "		72	115-120	
46 "				Par vagum cut.
52 "			75-85	Dog quiet.

These two experiments, in conjunction with what has been previously brought forward, certainly prove that jervia exerts a direct influence upon the cardiac muscle, lessening not only the rapidity but also the force of its pulsation.

In Experiment XLI. the pressure was reduced to a little more than a third of its primitive amount, and in Experiment XLII. a similar but less decided fall was seen. The temporary rise of the blood-pressure which occurred late in Experiment XLII. was undoubtedly due simply to the general muscular contractions.

In order to investigate still further, and determine more positively, the action of viridia upon the cardiac muscle, the following experiments were performed upon batrachians:

Experiment XLIII.—A rather large frog. The spine cut just below the head, and the heart laid bare. Two minute drops of a solution of jervia (three grains to the fluidrachm) were dropped upon the heart, which had been beating at the rate of eighty per minute. Instantly motion ceased, but in a few seconds re-commenced, and a minute afterwards the pulsations were sixty per minute. Shortly after this a little of the solution was injected into the heart, when movement ceased at once,

and only occurred again in the form of a few imperfect, distant pulsations. There was a not very well marked apical white spot, and the ventricles refused entirely to respond to mechanical stimuli. Movements of the mouth, apparently voluntary, continued some minutes after the cardiac arrest.

Experiment XLIV.—A moderate-sized frog. A few drops of the solution were thrown into the cardiac region. In a minute afterwards, voluntary motion not being markedly affected, the heart was exposed, and found to be beating twelve times a minute. About a half-minute after exposure, all spontaneous cardiac movements ceased, the heart continuing to respond to mechanical stimuli, and retaining this power for some minutes. Three minutes after the cardiac arrest, the frog made three rapid, successive, vigorous jumps.

Experiment XLV.—A frog of moderate size. About ten minims of the solution were injected into the pericardial space. Three-fourths of a minute, voluntary movements vigorous; one minute, spontaneous cardiac movements cease; two minutes, heart does not respond at all to mechanical stimulus; three minutes, feeble movements apparently voluntary; four minutes, frog sits up and opens his eyes widely, and when the balls are touched with a pencil the membranes respond, although somewhat sluggishly.

In the first of these experiments the effect of the direct application of the drug to the heart was very apparent. In the last two experiments the intention was, if possible, to paralyze the heart before the drug was carried freely into the general circulation. In this I was only partially successful, although voluntary movement persisted in a greater or less degree after complete arrest of the heart. Certainly, however, these experiments are confirmatory of those made upon warm-blooded animals, and show that viridia does act upon the heart itself.

Section C.—Action on the Vaso-Motor Nerves.

It is, of course, a matter of a good deal of interest and importance to determine whether viridia exerts an influence upon the vaso-motor nerves. It has already been shown that it lowers the arterial pressure by a direct action upon the heart; but this, of course, does not prove that it has no power over the blood-vessels, since it is very possible for the alkaloid to have a double action, affecting both the heart and the vaso-motor centres. It is evident, however, that the cardiac influence of the alkaloid must so mask any action upon the vaso-motor centres which it may exert as to render the proof of such action difficult.

In the following experiment the effect upon the blood-pressure of stimulating a sensitive nerve was taken advantage of to determine the point at issue:

Experiment XLVI.—A pup. Par vagum cut. Woorari administered so as to cause complete paralysis, and the dog kept alive by artificial respiration.

TIME.	DOSE.	PRESSURE.	REMARKS.
0	m.	95-115	A mild current applied to exposed femoral nerve.
½	"	160-170	Current broken.
4	gr. 1-10	95-105	Into femoral vein.
6	"	80-100	Current previously employed.
8	"	136	Maximum reached. Current broken.
16	"	40-50	

TIME.	DOSE.	PRESSURE.	REMARKS.
17	m.	gr. ⅓	Into peritoneal cavity.
19	"	35-45	
25	"	40-45	Current of strength previously used applied to a freshly dissected axillary nerve.
25¾	"	55-60	
26	"	40-45	Current broken.
29	"	20-25	Current applied to brachial nerve.
29½	"	30-35	Current broken.
30	"		
38	"		A mild current applied to pneumogastrics caused instantaneous diastolic arrest of the heart.
39	"	25-30	An intense current applied to a freshly dissected brachial nerve, on side opposite to that before used.
40	"	25-30	Current removed from brachial and applied to previously unused femoral.
41	"	25-30	Current broken.
43	"	25-30	Artificial respiration stopped.*
43¾	"	20-25	
43¾	"	15-20	
44¾	"	10-15	
45	"	9-12	Cardiometer removed.

Experiment XLVII.—A stout cur.

TIME.	DOSE.	PRESSURE.	REMARKS.
0	m.	85-90	Par vagum cut, and woorari, in small amount, given.
3½	"		Galvanism to femoral nerve caused some struggles.
4	"	100-140	Current broken.
6	gr. ¼	90-95	Injected into a vein; clot in latter so impeded progress that it is very doubtful whether any of the alkaloid got into the circulation.
13	"	90-103	
15	"	85-90	Galvanism as before.
15¾	"	110-140	Current broken.
18½	gr. ¼		Into vein; instantly struggles commenced, soon passing into violent convulsions, not preceded by any fall of the arterial pressure.
21½	"	160-165	Still convulsions. One-half grain of woorari.
26	"	75-80	Dog quiet.
28	"	65-70	
30	"		Violent convulsions, during which the mercury in the cardiometer rose and fell incessantly, reaching 185.
31	"	60	Dog quiet.
32¾	"	50-55	More woorari given.
34	"		Mild current to par vagum acted very decidedly on the heart.
46½	gr. 1		Instantly violent convulsions as before, not preceded by a fall of pressure.
46¾	"	145	
51	"	80	Dog quiet.
52	"	65	
60	"	55-60	Current applied to a fresh femoral nerve.
60½	"	85-90	
60¾	"	75-80	Current broken.
64	gr. ½		Injected.
76	"	40-50	
80	"	40-45	An intense current applied to a freshly exposed brachial nerve.
80¾	"	50	
81	"	50-55	
83	"	65	After this the mercury began to fall steadily, in spite of the continuous application of the current to the nerve.

In reviewing these experiments it will be found that in the first (*Experiment XLVI.*) a tenth of a grain was sufficient to affect decidedly the response of the circulation to the irritation of a sensitive nerve. The arterial pressure had only been lowered fifteen measures, yet a current applied as before the injection raised the column only to one hundred and thirty-five instead of one hundred and sixty. When a sixth of a grain more of the poison had

* This experiment compared with *Experiment XXVI.* shows the great difference between the action of the two alkaloids upon the heart, in that in viridia-poisoning an excess of carbonic acid in the blood is powerless to elevate the pressure in the arteries.

been exhibited, the rise produced by currents applied to the largest freshly-dissected nerves had scarcely any effect, and finally failed altogether, at a time, too, when the heart responded most readily to stimulation of the pneumogastriacs.*

In the second experiment, either because the drug used was less pure or the animal less susceptible, larger doses were required to effect the destruction of the reflex vaso-motor activity. It is, of course, possible that viridia paralyzes the afferent or sensitive nerves and thereby prevents the impulse being carried to the vaso-motor centre; but, as the animals show evident signs of pain when the nerve is irritated in viridia-poisoning, the two experiments seem to me to prove that viridia is a vaso-motor as well as a cardiac depressant.

In summing up the present study of viridia, the results obtained may be put in a very few words, as follows. Viridia in its action upon the circulation, as compared with its influence upon the respiration, is very much more powerful than veratroidia. The slowing of the pulse and the lowering of the arterial pressure caused by viridia are due to a direct action upon the cardiac muscles and upon the vaso-motor centres, upon both of which the alkaloid acts as a powerful depressant; upon the inhibitory and accelerator nerves of the heart, viridia acts not at all, or so slightly that its influence is not perceptible.

As has already been stated, Mr. Mitchell affirms that chemically there is no difference between viridia and the older alkaloid of veratrum album jervia. It is a matter of interest to test his conclusion physiologically, but, unfortunately, he has only been able to furnish me with sufficient of the veratrum album jervia to make a single experiment, as follows:

Experiment XLVIII.—Acetate of jervia from veratrum album in alcoholic solution. A stout cur; the cord cut in the upper dorsal region at 11.30 A.M. The first cardiometrical observation taken at 12 noon.

TIME.	DOSE.	PULSE.	PRESSURE.	REMARKS.
0 m.		186	65-75	
4 "			70-80	
5½ "	gr. ¼		80-90	Injected into femoral vein.
6½ "		150	70-80	
6¾ "			65-75	
7 "			60-70	
8 "			70-80	Dog trembling slightly.
9 "			70-85	
10 "	gr. 1-30	165	75-85	Into femoral vein.
10½ "			55-65	
11 "		93	35-45	
12 "		102	40-50	
15 "		105	45-55	
18 "		108	60-70	
19¼ "	gr. 1-30			Into femoral vein.
19½ "			50-55	
20 "		96	40-45	
21 "		99	45-50	
22 "				Pneumogastriacs cut.
22½ "		183	70-80	
23 "			60-68	
24 "		180		
25½ "	gr. 1-30		65-75	Into femoral vein.
26½ "		150	57-70	
32 "		126	60-70	

* I am very doubtful, however, whether a dose was not given about the twenty-seventh minute in Experiment XLVI. and omitted by mistake from the record.

TIME.	DOSE.	PULSE.	PRESSURE.	REMARKS.
34½ m.	gr. 1-15			Into femoral vein.
37 "		150	50-55	
40 "		150	50-55	A slight flow of saliva; it is possibly due to heat and to gag.
42½ "			50-60	
43 "	gr. 2-15			Into femoral vein.
44 "				A struggle; doubtful how much voluntary; it may be convulsive. Commenced in upper part of body and there confined, before the blood-pressure was affected by injection.

80 "				Cardiac pulsations ceased. Heart does not respond at all to strongest currents. The intestines in active motion, and respond well. Voluntary muscles respond well. The dog has not had violent convulsions at any time. During last half-hour has been perfectly quiet.

At the time this experiment was made, I thought more of the veratrum album jervia would be forthcoming, or otherwise the character of the experiment would have been different. In examining the record it will be seen that the drug produced a steady fall of the arterial pressure and lowering of the pulse-rate up to the time when the pneumogastriacs were cut, whereby the pulse was greatly accelerated. After the division of the inhibitory nerves the continuous exhibition of large doses failed to affect the pulse, although the pressure fell very decidedly, even, at last, to zero. When the arterial pressure was almost at a minimum, the pneumogastriacs were still sensitive to galvanic currents. Finally the heart was arrested, and its muscle was unable to respond to the strongest stimuli. As the reduction of the arterial pressure occurred after division of the spine, *i.e.*, paralysis of the vaso-motor system, it obviously was the result of a direct action upon the cardiac muscle. Making the obvious deductions from these facts, the above experiment would seem to indicate that jervia of veratrum album acts first as a stimulant to the cardiac inhibitory nerves, slowing the pulse through them, and that after their section it reduces the force but not the number of the cardiac pulsations.

If this be so, the alkaloids of V. album and V. viride are not the same, and Mr. Bullock is right. The conclusion cannot, however, be accepted as proven, since with the jervia was injected a quantity of alcohol, and it is possible that after section of the pneumogastriacs this alcohol may have increased the rate of

the cardiac pulsations. On the other hand, the convulsions caused by the true jervia were not nearly so violent as those ordinarily seen with viridia. So that, whilst confirmation is needed before any positive opinion can be reached, the evidence thus far points to the distinctness of the two alkaloids.

PART III.—GENERAL CONSIDERATIONS.

Having an intimate knowledge of the action upon the circulation of the only two active principles of *veratrum viride*, it would seem an easy task to determine the effect of the drug. Unfortunately, however, the exact proportion in which the alkaloids exist in the root is not known. Mr. Bullock obtained the viridia much more abundantly than the veratroidia, but Mr. Mitchell found the former alkaloid the least plentiful. Neither of these investigators claims that he obtained more than a portion of the active principles in the roots which he worked with, so that the question as to which alkaloid is most abundant seems doubly unsolved. It appears to me probable that the viridia is the more abundant, because in *veratrum viride* poisoning the circulation is affected so very much more intensely than the respiration.

Be these things as they may, it is plain that in those actions in which the two alkaloids agree, the crude drug will have most power, and, *vice versa*, if in any influences the two alkaloids are antagonistic, in such influences the *veratrum viride* will be least powerful. In what points, then, do the two alkaloids agree? Evidently in two,—namely, their depressing influence upon the force of the cardiac muscle, and upon the vaso-motor nerves.

Veratroidia lowers the pulse-rate by its action upon the inhibitory centres; viridia lowers the pulse-rate by benumbing, as it were, the muscle. These actions are not the same; it is even conceivable that they may to some degree be antagonistic, or, in other words, that a benumbed heart-muscle may not respond as quickly as normal to an inhibitory impulse. Any one who has used *veratrum viride* habitually must have noticed, more or less frequently, good effect produced by it before the pulse-rate was materially diminished. This, it seems to me, is explained by the above considerations, the arterial pressure being affected before the pulse-rate.

Although it might seem fitting to discuss the clinical uses of *veratrum viride* at length, yet I will refrain from so doing, for several reasons. In the first place, there is very little that is actually new to be said; in the second place, my own opinions have been sufficiently expressed elsewhere; in the third place, any doctor knowing the physiological action of this drug ought to be able to apply such knowledge to the treatment of disease. The practical value of the present study is in rendering clear and definite the clinical employment of the drug rather than in opening any new uses for it. It has been over and over again distinctly stated that the action of *veratrum viride* is that of a pure depressant. Yet its use in various *asthenic* diseases is still from time to time recommended in the journals. It hardly seems

necessary to stigmatize such practice as irrational and harmful. To weaken still further an already weak and struggling heart because the pulse-rate is high is simply murderous.

Before closing this article, I desire to call attention to the great similarity between many of the effects of *veratrum viride* and of depletion. If one-third of the circulatory fluid is withdrawn by bleeding, of course the inflamed part is more or less starved. *Veratrum viride* really withdraws the circulating fluid from the inflamed part almost as directly as does venesection. The capillaries of the inflamed tissue are distended, and the blood rushes to and accumulates in the part largely because the capillaries are thus distended. Under the influence of the *veratrum* the general rapidity of the blood-current is lessened, and of course the inflamed tissue feels this in its blood-supply; but, more than this, all the capillaries of the body are enlarged, and, claiming their share of the vital fluid, withdraw it from the inflamed part. If the average increase of the vessels should amount to one-third their original calibre, an effect in some degree similar to that produced by the removal through a vein of one-third of the blood ought to be obtained for the time being.

The extraordinary value of the drug in many sthenic conditions probably no one who has used it with cautious boldness will deny, and with our present light the *rationale* of its action seems very clear.

CASES CURED BY ELECTRICITY.

BY HUGO ENGEL, M.D.

Incomplete paralysis of both legs—Pes valgo-equinus—Lateral curvature of the spine.

IN October, 1873, I was called to see a lady. While attending her, my attention was called to her little daughter Mary, three years old. The child was creeping on the floor, and looked emaciated, or, rather, her face had that expression so often found in hunchbacked persons. The mother could give no history, except that the child had lost power suddenly ten months before.

The legs of the child were emaciated, the left more than the right, and the muscles of the back on the left side were less fully developed than those on the right side. The left foot was a beginning *pes valgo-equinus*. The seventh dorsal vertebra seemed to be painful, and when I tried to make the child stand on its feet there was at the same place a slight lateral curvature of the spine towards the right side.

A physician, when applying electricity in children, especially if he desires to establish a diagnosis with its aid, should be careful not to let the child see either the apparatus or the electrodes to be employed, and to make use of tepid water. When children once commence crying upon such an occasion they seldom cease, and any diagnosis in regard to electro-sensibility is impossible. The touch with a cold electrode will prevent the detection of a sensitive point.

I used a constant current of fourteen cells along the spinal cord, leaving the positive pole at the cervical region. I moved with the negative from vertebra to vertebra down to the sacrum. When I reached the sixth and seventh dorsal vertebræ, the child moved and screamed: here was the painful spot. I then ap-

plied the faradic current, with a dry electrode brush, left the positive (common) electrode on the cervical portion of the spine, and moved the negative (armed with the brush) all over the skin, with the following results:

The electro-sensibility was very much impaired all over on the left, and not at all on the right side of the back; the same disturbance of sensibility on the legs, but here it was disturbed, too, on the right one, only less than on the other; and normal electro-sensibility on the arms, face, and front of chest. I now wetted the common electrodes of the faradic current, for the purpose of trying the electro-muscular contractility. Every muscle contracted, but those on the right side more than those on the left, and the left tibialis anticus not at all. I now used a very strong galvanic current* (twenty-eight cells), and placed the two electrodes on the course of the ramus profundus nervi peronei sinistri. After a few moments the child seemed to suffer pain. Slight movements of the foot set in now when I interrupted the current, a sign that the tibialis anticus, the paralysis of which was the cause of the pes valgo-equinus, was not totally unamenable to treatment. When I now applied a strong faradic current over the muscle mentioned, the muscle contracted, and the foot assumed a normal position as long as the contraction of the tibialis anticus produced by the current counteracted the action of the peronei muscles.

As the electro-muscular contractility was nowhere lost, I gave a favorable prognosis, and commenced the treatment at once. I told the father of the child to put up in a room an enclosure similar to a large box with the top and bottom boards taken out, to make the sides of the enclosure perfectly smooth, and to place the child with its playthings within the enclosure, and under no circumstances to allow the child to walk until it should climb with its hands to the boards and commence to stand and to walk by itself.

This was October 21, 1873. I had the child brought to my office every day, and made use of the following treatment:

At first I applied the current of the constant battery (ten cells) over the spinal column. I placed the anode on the second dorsal vertebra and the cathode on the painful spot for ten minutes; then I used a current of twelve cells, and removed the cathode to the last lumbar vertebra, sometimes a little lower, to the sacrum, and towards the hip-joints for about two minutes.

I may as well state here that in about three weeks I had been obliged to decrease slowly the strength to six cells, the normal sensibility having been restored. I had to decrease in the same way the strength of the secondary induction current.

The latter was always had recourse to immediately after the action of the galvanic current, in the same séance. I faradized all the muscles of both legs and the muscles of the back on the left side. This procedure occupied about fifteen minutes. When I reached the left tibialis anticus I always sent at first a constant current over the region of the ramus profundus nervi peronei for about a minute, and then continued faradization as above mentioned.

The child was under this treatment for three weeks. November 12, 1873, the following amelioration had taken place. The surface-temperature all over the before-affected and in-temperature-lowered parts was normal. The child could walk a few steps alone, very timidly as yet, but without help; there was no curvature of the spine, and the left foot was but slightly abducted. The electro-sensibility of the parts had been

restored to the normal status, and the electro-muscular contractility of all the muscles was again a normal one, except that of the left tibialis anticus, which always required a stronger faradic current to produce the same contractions as its electrically stimulated confrater on the other leg. All the muscles had considerably increased in size.

I now had the child brought to me every second day, and, after two weeks more, twice a week. Once a week I applied the different currents as in the beginning of the treatment, only decreasing the strength of the currents; at the other sances I simply faradized the left tibialis anticus, and with such a good result that on Christmas eve following I discharged the child cured, and permanently so, as I had the pleasure of convincing myself a few days ago. During the last two weeks I had prescribed ol. morrhue and elix. cinchon. ferrat.

This case has, besides its result, some interesting points, which it may be worth while to mention here as useful hints in the application of electricity.

1. The case was one of spinal origin. There never had been any symptoms of brain-affection; the child was intelligent, and the muscles of the face were not affected.

2. There had been evidently in the beginning inflammation of the meninges at the seat of pain, with following exudation, extending farther down, and more on the left than on the right side.

3. The motor and sensitive nerves on the left side of the back especially suffered in consequence of pressure; therefore there were anæsthesia of the skin on the left side and paralysis of the muscles of the same side, and the muscles on the right drew the spinal column laterally to their side. When those of the left side were in their normal condition again, the curvature of the spine ceased. The same phenomenon took place with the pes equinus, which had a similar origin, the tibialis anticus being paralyzed, and the antagonistic muscles acting alone abducted and turned the foot outwards. As soon as this paralysis was overcome, the foot regained its normal position.

4. The galvanic current had a catalytic (electrolytic) effect on the exudations of the spinal cord, and a conduction-exciting influence on the motor nerves of totally paralyzed and perhaps degenerated muscles.

5. The faradic current improved the nourishment of the paralyzed muscles, which could regenerate their fibres.

CASE OF SUPPOSED OPIUM-POISONING. —USE OF ATROPIA.

BY J. S. RAMSEY, M.D.

WILLIAM G., aged 48; occupation machinist; unmarried. Has been strictly temperate until within about a year, since which time has been addicted to the occasional immoderate use of strong drink. Has rarely extended his "sprees" beyond a period of five or six days, then ceasing the use of liquor for a varied time ranging from one to four months.

On Monday, August 3, 1874, about 10.30 P.M., I was called to see the above-named in consultation with Dr. B. F. Witmer, formerly of Millersburg, Pa., and obtained the following history of the case. Patient had been on a continuous spree since the previous Monday; at no

* Several inquiries having been made, I will here mention that by "constant" or "galvanic" current I mean the current generated by the large constant battery manufactured by Otto Flemming, No. 13 North Ninth Street, Philadelphia. The cells thereof are stronger than Daniel's elements, in the proportion of about Flemming two and a half, Daniel four.

time worse than in an exhilarating state of inebriety. He had not been drinking more than usual on the day I first saw him, but had returned to his boarding-house and lain down and slept during the afternoon, arising well sobered about 5 P.M. He shortly after went out, and in about an hour was found by friends in a saloon (of indifferent character), in a condition which rendered it necessary that he should be assisted to his home. Here he was allowed to lie on a lounge and sleep. In this way he remained until shortly after 10 P.M., when it was noticed that he was breathing peculiarly, and that his face was of a bluish purple.

On examination, we found him wholly unconscious; pupils firmly contracted to the size of a pin's head; respiration varied, at no time more than three, and on several carefully-noted times only one a minute. Pulse 120; breathing stertorous and puffy; all sensation was absent, and respiration was unaltered on the application of handkerchief well saturated with spirits amm. arom. We attempted to administer remedies by mouth, but failed, he being unable to swallow. After many fruitless attempts to rouse him, as a final resort we administered hypodermically one-thirtieth grain of atropiæ sulph., and, immediately following it, an injection per rectum of spts. amm. arom., $\frac{3}{4}$ ss in a pint and a half of strong soap-suds. In less than half an hour after injections, the *respiration increased to fifteen per minute*, and the pupil dilated to the natural size; at the same time the patient became semi-conscious, and on the following morning he was so far recovered as to be able to go on his usual way.

The question naturally arises, Was the case one of opium- or of alcoholic poisoning? Mr. G. since informs me that the only thing he drank was one glass of ale. The history of the case, with the subsequent result, certainly points most strongly to the former, especially as he is known to have lost quite a large sum of money at the time.

An important point to be noted is the rapid increase in the respiration, and subsequent recovery, after the injection hypodermically and per rectum.

TRANSLATIONS.

THE TREATMENT OF SNAKE-BITES BY HYPODERMIC INJECTIONS OF AMMONIA (Dr. Kleinschmidt: *Berliner Klin. Wochenschrift*, No. 24, 1874).—On the morning of the 24th of July, Dr. Kleinschmidt was called to a boy aged 9 years, who, while plucking berries during the previous day, had been bitten by an adder. Upon his arrival, he found the patient sitting up in bed, with a fixed gaze, and with his countenance covered with cold sweat. The entire right upper extremity was greatly swollen, the skin being tightly distended and of a bluish color, and upon the least movement the boy uttered loud shrieks. The circumferences of the arm and fore-arm of the right side were found to be thirty and thirty-two centimetres respectively; the measurements taken at corresponding points upon the left limb being sixteen and fifteen centimetres.

The swelling upon the right side extended beyond the arm and over the right breast and side, and upon these localities there was also noticed an eruption, somewhat similar to that of nettle-rash; the axillary glands of this side were also involved. The position of the bite could not be seen, but the bystanders said that it was upon the middle finger, upon which, as well as upon the dorsal surface of the hand, several bullæ

were to be seen. Under these circumstances, there could be no indication for cutting out the wound, nor for cauterizing it, and since, in a case of adder-bite which had been treated but a few days before, but in which the symptoms were much less threatening, leeches had seemed to be of service, they were ordered to be used. The child also took, by the mouth, solution of caustic ammonia and small pieces of ice to counteract the tendency to vomit which was present, and, as the bowels were constipated, a laxative was administered.

When the patient was seen the next day, it was found that he had passed a restless night, and that his condition had become more serious. The swelling of the wounded limb was more marked; the circumference of the arm being thirty-two, that of the fore-arm thirty-four centimetres. The entire right side was more swollen, and the scrotum, which on the previous day was free, was now also involved. The features of the patient presented an indescribable expression of anxiety; the pulse was small and quick, beating 120, and the temperature was 39.9° C. If the swollen part of the body was touched, the boy gave utterance to still louder screams than upon the preceding day. A renewed application of leeches was ordered, and the amount of the solution of caustic ammonia to be taken was increased. Dr. Kleinschmidt then returned to his house, and, while reading a medical journal, met with an article upon the treatment of snake-bites by means of the hypodermic use of caustic ammonia. He at once seized his hypodermic syringe and hastened to the patient, and, having filled the instrument with a solution of caustic ammonia, he injected the entire quantity beneath the skin of the axilla. After the expiration of half an hour, under the constant application of cold compresses, the pain seemed to be somewhat less, and about the wound made by the syringe was noticed a bluish tinge. In the evening of the same day the child had ceased to vomit, the expression of anxiety upon the features was not so marked, and no increase in the amount of swelling had taken place. On account of the intense pain which was still present in the swollen arm, small punctures were made in the skin, and through them a greenish-yellow fluid slowly discharged itself.

The next morning the boy was comfortable, and, upon measurement, it was found that the injured arm had decreased in size. Much fluid had come away during the night, and the patient had slept much more quietly than had previously been the case since his accident. At the point of entrance of the syringe a large black slough had formed, but no pain at this point was complained of. The pain in the arm was much more moderate, and was present only in response to severe pressure. A marked improvement was noticed in the general condition of the child, the vomiting had ceased, and the appetite was good. During the next eight days the swelling of the limb gradually diminished, until it became of about the normal size, the bluish-green color of the skin yielded to a greenish yellow, and the child could again use the limb freely.

Dr. Kleinschmidt concludes that, although (since but four per cent. of persons bitten by snakes of this kind die) it cannot be said that this boy would not have recovered under a purely expectant treatment, still, the solution of caustic ammonia must be considered as the most efficacious antidote against the poison of serpents, and the one, too, which is the most speedy in its action. He will be inclined in the future to use this treatment, not only in cases of dissecting-wounds and of hydrophobia, but also in malignant pustule and glanders, in which diseases we are all so much at a loss for a remedy that shall be certain in its effects.

W. A.

PRIMARY INFECTIOUS INFLAMMATION OF BONES AND OF THEIR MARROW.—Under the above title Lücke (*Deutsche Zeitschrift f. Chirurgie*, iv., 1874, pp. 218–245) describes a disease which is very variously named by authors, but which perhaps is best known by the name of spontaneous osteomyelitis. Lücke regards the disease as one due to infection which takes its start from the marrow or periosteum, which has hitherto been intact. It is possible for the disease to remain limited to the locality at which it originates, but it is quite common to meet with secondary deposits before suppuration has been established at the point originally involved. The disease occurs only in youth up to the time that the growth of bone is complete. Its occurrence appears to be favored by damp, cold weather, and it is consequently most frequently met with in the spring and autumn; but from this it must not be inferred that it is not liable to be met with during the other seasons. Heretofore, the affection has been thought to be caused by the influence of cold exclusively, and Roser on this account speaks of a pseudo-rheumatic inflammation of the joints and bones. Lücke has, however, in a series of cases been able to establish the fact that an injury has served to start the disease into action, and he infers that both these causes are concerned in leading to the local disturbances of circulation whence the affection is developed. Consequent upon the injury is a period of incubation of two or three days, then after a chill an intense fever sets in, which speedily becomes typhoid in its character. The formation of a differential diagnosis between this affection and typhus is sometimes difficult, but it can generally be made by noting the existence of the local trouble early in the attack. The presence, however, of this local inflammation may cause the disease to be looked upon as acute articular rheumatism. Catarrh of the lungs sometimes sets in early in the disease, and may be quite evanescent, or, on the other hand, may speedily lead to a fatal issue. The cause of this occurrence is to be sought in a fatty embolism of the lungs, as was established in two cases by post-mortem examinations; and Lücke believes that the process originates in a solution of the fat-cells of the marrow, and the entrance of free fat into the veins. The local symptoms begin with the chill, which at the most has been preceded by but slightly painful sensations, which from this time become rapidly more severe. The starting-point of the affection is either in the periosteum or the marrow, but the second of these tissues is usually involved in the process. The long bones are the most apt to be affected, and these most frequently at their lower extremities, while the involvement of the spongy bones is more rare. It usually results in suppuration with necrosis of a greater or less extent, and if the epiphysis is the part attacked its separation is a usual occurrence. The neighboring joint of course is commonly involved, and this can take place even when the disease is seated at some distance from the articulation. It is possible that the disease may be confined to the primary deposit, and run a favorable course; but usually, even before suppuration at the starting-point occurs, secondary deposits are found in other bones, in some of the soft parts, or, worst of all, in the internal organs. These secondary deposits may also be preceded by chills, and then some of the appearances of pyæmia are presented. Lücke is inclined to look upon the whole process as pyæmic, especially since he has succeeded in finding micrococcus in the marrow at a time when there had been no communication with the outer air; and from this analogy with pyæmia, he thinks himself justified in regarding the process as one of infection. W. A.

NEW METHOD OF LIGATING THE PRIMITIVE CAROTID ARTERY (*Bulletin de la Soc. Méd. de la Suisse*—

lande, 1873, No. 11).—In a paper read before the Medical Society of Southern Switzerland, Dr. Rouge, of Lausanne, proposes the following new method of ligating the primitive carotid artery, a method which is as feasible for ordinary cases as the one usually employed, and is claimed to be much less dangerous and more easy of execution than the operation of Sédillot, in which the ligature is applied to the inferior half of the vessel between the origins of the sterno-cleido-mastoid muscle. In numerous cases he thinks that this method is the only one that can be recommended. As yet, indeed, no opportunity has occurred of testing the operation upon the living, but Dr. Rouge has performed it many times upon the cadaver, and always with the same result. The head being strongly extended, and at the same time turned towards the opposite side, an incision is to be made, usually about opposite to the thyroid cartilage, along the posterior edge of the sterno-mastoid muscle, which, owing to the position of the head, is strongly prominent. The vessel can then be reached without trouble by working forwards and inwards along the inner surface of the muscle; no annoyance is experienced from the jugular vein, which goes to the front without any special effort on the part of the operator, and the artery can be readily isolated and secured by the ligature. The introducer of this method thinks that it should always be employed when tumors situated in the anterior cervical region present serious difficulties in the performance of the usual operation. This is apt to be the case when these tumors are of strumous origin (and tumors of this class are extremely frequent in Switzerland), and here, too, the carotid artery is found out of its usual place, being thrust backward to a greater or less degree. Dr. Rouge claims also that his method has the advantage of permitting the application of the ligature at various distances below the bifurcation of the artery, and at the same time the drainage of the wound is facilitated by its situation. As a final advantage, it may be urged that the cicatrix left by the wound of incision would lie more to the side and back of the neck than usual, and by the projection of the sterno-cleido-mastoid muscle would be less strikingly visible. W. A.

IGNIPUNCTURE (G. Juillard: *Centralblatt für Chir.*).—Some time ago, Richet advised a mode of treatment for chronic affections of the bones and joints, to which the name of ignipuncture was given. This mode of treatment was carried out by punctures into the affected parts, made with a glowing needle. The instrument used by the originator of the treatment, Richet, was a needle of platinum, four or five centimetres in length, which was attached to a ball for the purpose of retaining heat. Juillard had made for the same purpose a very narrow-pointed loop of platinum wire, which he heated as in other galvano-caustic operations, and which he found much lighter and much more easily manipulated than the needle which was previously used. The operation is performed by introducing the glowing needle into the tissues to a sufficient depth to penetrate into the affected joint or into the diseased bone, and then by at once withdrawing it. This operation is to be repeated many times if it is found to be necessary. The pain attending it is not very intense, an anæsthetic not being always needed. After the operation, the limb is to be kept at rest, and cold compresses are to be applied over the part. If there was any exudation either of a serous or purulent character present in the joint at the time the needle was introduced, it made its exit through the opening; but it usually ceases to flow at the expiration of ten or twelve hours, and only in exceptional cases was the operation followed by a fistula. The perforations usually healed by first intention, and when they were followed by fistulæ it was because the needles

were left in the tissues for too long a time. Ignipuncture is usually followed by a marked diminution of pain and fever, and there is no inflammatory reaction consequent upon it.

The results of this operation are reported to be very encouraging. The cure of affections of the joints usually results in ankylosis, but sometimes motion is preserved. Favorable results can be looked for with more confidence when the affection is an arthritis of a purely purulent or fungous form, but it is often necessary to repeat the introduction of the needle four or five times. Even when a complete cure is not attained, some improvement often follows, and in no case are there any ill results.

W. A.

THE ACTION OF MONO-BROMIDE OF CAMPHOR.—M. Bourneville gives (*Le Progrès Médical*) a series of experiments performed by himself on various animals, to whom he administered various doses of this substance, with a view to ascertain its physiological action. His conclusions are as follows. Bromide of camphor diminishes the number of pulsations of the heart, and determines a contraction of the auricular vessels (guinea-pigs and cats). It diminishes the number of inspirations. It lowers the temperature uniformly in fatal cases. This lowering goes on to a greater and greater degree, to the end. In cases which recover, this period of lowering is succeeded by one of elevation of temperature, which returns to the original point, but in a longer time than that during which the abatement has operated.

Bromide of camphor possesses incontestable hypnotic qualities. Toleration is not established with this medicine, and its use gives rise, at least with guinea-pigs, to a rapid, progressive emaciation.

THERAPEUTIC NOTES.

HYDRASTIN IN GONORRHOEA.—As far as internal treatment is concerned, I merely give in the first stage a saline aperient, to be continued three times daily for four or five days, together with the following injection: hydrastin, one drachm; solution of morphia (Magen-die's), two drachms; acacia mucilage to four ounces: to be used three times daily. This I have employed when inflammation ran very high, without even the slightest ill effects, and have used it in every stage of gonorrhœa with the most beneficial results when every other treatment, both internally and locally, had failed, including red sandal oil. But there is one remark I wish to make regarding the use of injections which medical men generally forget, and that is, to tell their patients to micturate previous to its use. Unless this is done, injections in gonorrhœa are useless. Hydrastin is used very much in different parts of the United States, and very successfully. My last patient was a farmer, who had had a gleet discharge for seven months. His medical man had quite wearied him out with injections, etc., all to no purpose. I at once tried the hydrastin, and in two weeks he was quite well.—*J. N. Bredin, L.R.C.S.I., etc., in London Lancet.*

TO CHECK VOMITING FROM COUGH.—Consumptives and others suffering from paroxysms of cough frequently vomit their food in such paroxysms. Dr. Woiliez recommends swabbing the pharynx, before eating, with a concentrated solution of bromide of potassium,—

R Pot. brom., ʒij;
Aquæ destil., ʒiv,

—warning the patient not to cough for a few minutes

after the application. The same treatment is recommended for the vomiting of pregnancy. It is said to be very successful.—*Missouri Clinical Record*, August, 1874.

Sodii bicarb., ʒi;
Cretæ præparat., ʒi, gr. xv;
Pulv. sacch. alb., ʒiiss.

M.—Div. in chart. no. x. One to be taken half an hour before meals in acid dyspepsia.

ANTISPASMODIC PILLS.—

R Pulv. assafoetidæ,
Pulv. camphoræ, āā ʒvi;
Ext. belladonnæ, ʒii;
Pulv. opii, ʒi;
Syrupi, q. s.—M.

Ft. in pil. no. clxxx.

One to be taken the first day, two the second, etc., until six are taken daily or two or three times a day. Useful in hysterical and spasmodic nervous affections, in connection with bromide of potassium in doses of ten to fifteen grains.

IN HYSTERIA.—

R Chloride of gold and sodium, grs. iv;
Gum arabic, ʒi;
Sugar, q. s.—M.

Divide into forty pills, of which one may be taken three or more times a day.

SUBCUTANEOUS INJECTIONS OF APOMORPHINE.—M. Garville recommends the hypodermic use of apomorphine as an emetic. In cases of poisoning where it is impossible to administer medicine by the mouth, this remedy may prove of the highest value. An injection of one-sixth of a grain in one scruple of water will produce copious emesis within five minutes.

. PHILADELPHIA

MEDICAL TIMES.

A WEEKLY JOURNAL OF

MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY

J. B. LIPPINCOTT & CO.,

715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, SEPTEMBER 12, 1874.

EDITORIAL.

AID FOR THE DESERVING.

WE hear it rumored that the managers of the Homœopathic Hospital in this city intend to appeal to the citizens for pecuniary aid. If we mistake not, the institution has already tasted the sweet sustenance that flows from the legislative fountains of our good mother the State of Pennsylvania. To aid in the good work of raising money for a deserving charity is always pleasant and profitable, and we propose to-day to give a few facts concerning this hospital, so that our readers may be able to say a word or two for it whenever opportunity offers. We do this the more willingly because, if reporters are to be at all believed, the hospital is especially under the patronage of our worthy Mayor.

On the 26th of last May a young girl named Lizzie Tamplin was shot, and taken to the Homœopathic Hospital. In the course of a few days afterwards she died, and, a certificate of death from hemorrhage of the lungs having been given by the physician of the Homœopathic Hospital, her funeral was announced. Coroner Brown happened to see this announcement in the *Ledger*, and, about an hour before the time appointed for the burial, entered the house, and actually took the body out of the coffin, surrounded by the relatives. At the autopsy, a bullet was found in the brain; the hole in the skull had been filled with lime, and a piece of flesh-colored plaster placed outside, so as to con-

ceal it. We believe this case is to go to the courts, and hope our worthy neighbors will have justice done them.

A few weeks since, a policeman found, near Twentieth and Market Streets, a man named James Culliman, suffering from a frightful lacerated compound comminuted fracture of the thigh, and other injuries, the results of a fall out of a fourth-story window. The order of the Mayor being to take "accidents" to the Homœopathic Hospital, the injured man was conveyed there, about three o'clock A.M. During the whole of Sunday he was left in the hospital without any measure of relief being adopted until about ten o'clock in the evening, when, without a consultation of surgeons, the limb was amputated by a person not connected with the hospital; the patient dying about one o'clock the same night. It does not seem very remarkable that the Coroner's jury brought in a verdict that—

"The said James Culliman came to his death, August 17, 1874, from the combined effect of shocks received by a fall at No. 1917 Market Street, August 16, 1874, and from the amputation of his limb performed at the Homœopathic Hospital. *In the opinion of the jury, the delay of the physicians in charge of the hospital in their application of medical treatment to the deceased is in the highest degree censurable.*"

Lieutenant Wilkins of the police visited Culliman at the hospital during Sunday. He states that he was told by the doctor in charge "that he could not treat this and other cases until the visiting surgeon was consulted. I said, 'Then the man must lie here and die.' He said, 'No; in case of actual necessity I could call somebody in to do it.' We then talked about the case, and he said that the man was as easy as he could be under the circumstances, and he had no fear of his life."

In these cases, sufficient legal inquiry has been made to render the facts indisputable.

The following is given by a reporter for *The Sunday Press*:

"On the night of May 2, 1873, James Campbell, an elderly man, was hit on the head with an axe, in a quarrel with his son-in-law, at his house in a court running off Race Street above Fifteenth Street. Campbell was by the police taken to the Homœopathic Hospital, and the news telegraphed to the Central Station. A dozen reporters, hungry for a murder, after getting down to all the facts of the assault, visited the hospital in order to ascertain what immediate danger there was of the man dying that night and thus giving them a sensation for the morrow. The writer of this article was one of the anxious craft of that night. He visited the Homœopathic Hospital, and interviewed the doctor in charge. 'The man will die before morning,' said

the doctor; 'I can do nothing for him, and it would be only uselessly cruel to attempt by even dressing his wounds to save him.'

"Within one week, James Campbell escaped from this hospital alive. His smashed skull was simply a glancing scalp-wound."

At the trial of Sergeant Rogers of the police for killing Tweedy, it was a matter of evidence that the latter lay two days at the Homœopathic Hospital before his wounds were dressed.

When through the cracks so much light shines, one can well conceive how brilliant the illumination would be if the view were unobstructed. Will not, then, our readers do what they can to aid this impecunious and most deserving charity? Probably the Mayor would gladly receive donations.

CORRESPONDENCE.

THE BRITISH MEDICAL ASSOCIATION, FORTY-SECOND ANNUAL MEETING.

NORWICH, ENGLAND, }
Thursday, Aug. 13, 1874. }

DEAR SIR,—The British Medical Association meets for the second time in the ancient city of Norwich, the first session having been held twenty-eight years ago. Norwich may be called the metropolis of the east of England, and was in the seventeenth century, as Macaulay writes of it, "the chief seat of manufactures of the realm." But the star of progress which ever leads westward has left in favor of the great manufacturing centres far away from it. Although still prominent in a few special lines of industry, it is now mostly known by its traditions and by its grand old remains of the past. Norwich strikes the traveller, particularly if he be an American and fresh from the newness, baldness, and bareness of our neoplastic development, as singularly quaint and ancient; and it is the type of the few remaining cities of England that retain their original architectural characteristics not destroyed before the march of modern improvement or crumbled by the eroding hand of time. The labyrinthine interlacement of narrow and tortuous streets, which are almost without sidewalks, the number of ancient cathedrals and churches with belfries chiming the echoes of centuries ago, the overhanging walls of low-browed cottage-looking dwelling-houses with peaked gables, all tend to a feeling as if the dial of time had been here turned backward to "the good old times" of a few centuries in the past.

Here is the old Norwich Castle, on the spot of a fortification built by "Uffa, King of the East Angles," in the year 575, and where Alfred the Great built a stronghold that was destroyed by Sweyn, the Danish king. Then Canute, in 1018, erected a castle, the core of which still stands in ornate architectural beauty within the present structure. Seven centuries ago it was, as

now, a prison, and in the reign of "Good Queen Bess" a record shows the imprisonment of some offenders who were "commytted for refusing to come to church in time for prayers;" and the philanthropic John Howard, in his humane visitation of prisons, complained of "an underground dungeon, in which the inmates descended by a ladder, the floor of which was often one or two feet deep with water."

The Cathedral of Norwich is eight hundred years old, and its imperishable walls are partly of flint that retains almost the original lustre of the fractured surfaces of the stones.

Norwich has a classic reputation for its great names of the past, and among those still living are some of the ablest and best-known medical men of this country. Dr. Cains, of Cambridge notoriety, was born here in 1510; Sir Thomas Browne was a Norwich physician; and the names of Martineau, Rigby, Dalrymple, Lubbock, Yelloby, and Crosse will ever be remembered.

Elaborate arrangements are made for conducting the business of the Association in various rooms for the general meeting of the body, and for the various sections of medicine, surgery, obstetrics, and State medicine, and there are also the most generous preparations for dinners and entertainments for the members and visitors. Private hospitality that will take no refusal stands with open doors and outstretched hands to welcome the stranger to those charming old English homesteads, and the home-like greeting that disarms all formality and blends him at once in family intimacy is something that requires the delightful experience for its appreciation.

A pleasant coincidence that adds to the gala character of the occasion is the arrival in the city of H.R.H. Prince Arthur, with a regiment of cavalry, who are to make permanent quarters here.

An important and interesting adjuvant of the meeting is the Annual Museum of articles arranged in the following classes: medical and surgical instruments and appliances; chemicals and apparatus; drugs and articles of diet; microscopes and apparatus, and microscopic specimens; calculi; general pathological specimens, casts, etc.; pathological photographs, drawings, and diagrams; drawings and models of ventilation; ancient instruments; miscellaneous.

I notice among the large number arriving such prominent members of the profession as Sir William Fergusson, Sir James Paget, Druitt, Reynolds, Croft, Sibson, Duncan, Barnes, Southam, Tupe, Quain, Barwell, Macleod, Tait, Hewitt, Sims, Parker, Lawson, Kidd, Haughton, Hart, Tufnell, Bennett, Aveling, Buchanan, Foster, Cormack, Lund, Steele, Nales, Stewart, Clarke, Haviland, Falconer; and such resident members as Cadge, Bateman, Copeman, Master, and Crosse are in attendance. About three hundred are at this time enrolled.

The meeting was opened by the president, Sir William Fergusson, in an eloquent address, alluding to the classic memories of the place, and particularly to its high professional character, developed by the line of

great surgeons whose names I have already mentioned. The distinguished and dignified bearing of the speaker, with his fine personal appearance, his tall, handsome, erect figure, his snowy hair, broad forehead, bright dark eyes, and pale intellectual face, make him a fitting personage to initiate the business of this important assemblage. It may be interesting to those who have not seen Sir William Fergusson to know that his resemblance to the late Dr. Wilson Jewell, of Philadelphia, is most decided and striking.

Then followed the address of the President-elect, Dr. Copeman, of Norwich, in which he considered some matters of sanitary science, and, alluding to the necessity, in the advanced stage of the science, of the division of labor in making physiological and clinical investigations, said,—

“When we consider what large numbers now belong to this Association, and the great amount of mind and talent embraced in it, it is difficult to say what are to be the limits of its usefulness and of its responsibility. It no doubt behooves us, individually and collectively, to turn over in our minds how we can best contribute to the accomplishment of the great results expected of us. Two things strike me as especially needful: first, that we should attempt the elucidation of many phenomena we meet with, by earnest physiological research; and, secondly, that we should endeavor, above all things, to add to the not too ample store of practical facts in the use of remedies for the cure of disease. These two departments of study cannot be fully undertaken by the same individuals.

“Physiological research, to be worth what it ought to be, requires the close application of vigorous minds adapted to the science and imbued with a love of it, but free also from all anxiety about the ways and means of providing for their daily wants and necessities. All so engaged ought to have, or be provided with, sufficient means to enable them to devote their whole time and attention to their work, without the cares and troubles of practice; whilst, on the other hand, those who are engaged in the great and paramount object of curing disease cannot possibly spare the necessary time for minute physiological investigations. Each, however, can materially assist the other: the practitioner can furnish facts and observations which may greatly assist the physiologist in his experiments, and the latter can enlighten the former by giving reasons for the facts presented to his notice. The majority of us must be practitioners, and earn our living by practice; but I should hope, in a society like ours, means will ere long be found to supply the necessary funds to a certain number of young and healthful minds, congenial to the work, to enable them to devote their time and energies to physiology as a separate study.”

On the second day of the meeting, Dr. Russell Reynolds delivered the address in medicine, which was a beautifully philosophical reasoning on the mystery of life. He repudiated the idea of life being nothing more than an aggregation of the resultant movements of heat, light, electricity, etc. Impressions from without, he

said, may determine the occurrence of motion or sensation; but the secret of life is still hidden in the organism which transmits the one into the other. Physical force may be correlated to vital acts, but life itself is the special property or condition of the special material which effects that peculiar relation, and it is as far from comprehension now as it was a thousand years ago. Heat applied to a fertilized and living egg may set in motion all those chemical and physical changes and movements which make up the living processes of a growing bird; but if the egg be not living to begin with, heat but hastens another series of chemical changes,—those of disintegration, putrefaction, and decay. Life is still hidden in the wonderful cells from which all these changes of structure and function take their start. If we apply electricity to a nerve-trunk or a cerebral convulsion, motions of a definite character may result, but the secret of life still lies hidden in the properties of those nervous elements. Every so-called chemical “elementary body” is known only by its power of so modifying forces and material as to be distinct in its sum of properties from every other elementary body. Each of them has in itself a “something” which makes it what it is, and to which we unconsciously refer in thought when we give them names and places in scientific categories. This “tendency to individuation,” as it has been called, is what constitutes that which has been termed their “life.” The same mode of thought is true with regard to the living organic body: that which makes it living, which alone justifies the attribution to it of the properties of life, is the possession of an individual power of behaving in such a way under given circumstances, and amidst the brunt of conflicting forces, and surrounded by varying materials, that it evolves the phenomena we designate as vital. Many are disposed to think that if we could only make our experiments a little more clever we may get rid of the term and the idea of life itself, and so make a great advance in science. It may be that this will be done; but Dr. Reynolds believes that it will not, that there will ever remain the same kind of mystery with regard to life itself as that which still shrouds the nature of the simple forces.

The General Secretary, Mr. Fouhes, read the report of the Council, the president of which is Mr. Southam, of Manchester. The report stated that the Association now numbered between five and six thousand members; that its financial condition was satisfactory; that the income of the past year was \$42,000; and it was proposed that a grant of one thousand dollars be made in aid of researches in medicine and the allied sciences.

It was unanimously resolved that the next meeting of the Association shall be held in Edinburgh, under the presidency of Sir Robert Christison.

In the Section of Medicine, the President, Dr. Eade, considered the nervous system in reference to practical medicine, and alluded to the prevailing tendency of medical investigation in that direction as illustrated by the papers about to be presented at the meeting. He remarked that, “The more exact knowledge which we

now possess of the brain and its subdivisions, as well as of its vascular supply and distribution; also of the functions of the ganglionic and vaso-motor nerves; together with the ascertainment of the great principle that vascular supply is regulated by the inhibitory action of the nerves, and that removal of this governing influence and control admits of ungoverned local action, *i.e.*, disease—have been sufficient to stimulate to fresh and active inquiry in this direction. And well it may be so, when we see that many previously obscure diseases (notably chorea and epilepsy, and many varieties of paralysis) have been already rendered more intelligible through this knowledge, and that the whole process of inflammation itself is in a fair way of being at length referred to its evidently proper position of a paresis or functional paralysis."

The opening of the proceedings of the Section on Surgery was by Sir James Paget, who referred to his first surgical training in Norwich, before he left it for his after-studentship in London, and compared surgical practice of that day with the present. He referred to his early careful and full notes of cases and observations made here, and said, "I found there some things which made me fear lest in our progress we should have let fall some of the things which we had better have held, and are now regarding some things too lightly that then seemed very grave, and perhaps are so still. For among the records which I found are records of methods of practice now almost completely disused, and yet in which I feel confident there was much right. I find, for example, a large and almost uniform practice of bleeding for all acute diseases, for many chronic, for most of those that were unknown or uncertain, and for a large proportion of cases in which there seemed to be nothing the matter. Trying to learn something from these things, I came to one or two conclusions which I am sure the younger members of the profession need to have much impressed on them. One of them is that at the present day we undoubtedly over-value the blood and estimate too cautiously the loss of it. I will venture to say that there are few persons in this room who might not be bled to fainting, and to-morrow be almost unconscious of it, and perhaps, in this week of hospitalities, might even be the better."

R. J. LEVIS.

SELECTIONS.

PARTICULARS OF A CASE IN WHICH CARBURETTED HYDROGEN WAS FORMED IN THE HUMAN STOMACH—A READY METHOD OF WASHING OUT THE STOMACH.

TOWARDS the end of last year, a man presented himself, during the consulting-hour of Prof. Frerichs, who declared that he had both a gas- and a vinegar-manufactory in his stomach. These, he said, worked alternately, so that at one time he brought up quantities of strongly acidulated matter, at another he belched quantities of gas which burnt, when a lighted match was applied to it, with a brilliant flame. In

proof of this latter assertion, having twisted a piece of paper into a roll and placed it like a gas-burner in his mouth, he applied, at the moment of an eructation, a match to its end, when a brilliant bright-yellow flame, fully a foot long, burst forth.

There could be no doubt that we had here to do with a case of abnormal digestion, with the formation of stable and unstable products of fermentation; the question being, what was the nature of the latter. For though the eructation of inflammable gas from the stomach has already been observed, and the gas itself analyzed (*vide* the analysis of Carius and Popoff), still the color of the flame has invariably been a pale blue, showing the great preponderance of hydrogen; whereas in this case the yellow color of the flame seemed to show the presence of carburetted hydrogen.*

The physical examination of the patient disclosed a very distended condition of the stomach, to account for which it seemed probable that there was a narrowing of the pylorus, caused by the contraction of a cicatrix of an ordinary round ulcer.

As I have for some time devoted myself to gasometrical analysis (*vide* my works "Ueber den CO₂ gehalt des Harns im Fieber," and "Beiträge zur Gasometrie menschliches Transudate," in Reichert and Du Bois-Reymond's *Archiv für Physiologie*), the chemical examination of the solid and gaseous excreta from our patient's stomach was confided by Prof. Frerichs to my colleague, Dr. Russstein, and myself.

The analyses were conducted in the usual manner, the gas being collected over quicksilver by means of a pipe from the patient's mouth, and gave the following volumetric results:

First Analysis.				Second Analysis.			
CO ₂	.	.	17.40	.	.	.	20.57
H	.	.	21.52	.	.	.	20.57
CH ₄	.	.	2.71	.	.	.	10.75
O	.	.	11.91	.	.	.	6.72
N	.	.	46.44	.	.	.	41.38
With traces of SH ₂ .							

In some of the matter vomited by the patient some days afterwards, we were able to demonstrate the presence of lactic, butyric, and acetic acids, and some of their homologues (not, however, quantitatively determined), sugar and dextrose.

Under the microscope all the well-known elements of food undergoing fermentation in the stomach were observed, of which I will only mention some very large specimens of sarcina ventriculi, the yeast fungus, and rod-shaped (stäbchenförmige) bodies, having the appearance of bacteria (the lactic acid fungus of Pasteur?).

[Dr. Ewald here enters upon an elaborate discussion of the fermentative changes resulting in the production of the gas in the stomach. This we omit.]

The treatment consisted in regulating carefully the patient's diet, and washing out the stomach by means of the stomach-pump. Under this treatment the discomfort he suffered was greatly lessened, and only once afterwards did he bring up inflammable gas, which, however, burnt with a blue flame. As he soon became quite an expert in introducing the stomach-pump, he has left us, and gone to the country to further recruit his health.

I will draw your attention to a very simple and readily available method of washing out the stomach, which I now always adopt, and which, on account of its great simplicity, seems likely to make the topical treatment of diseases of the stomach, especially in cases of poisoning, much more common. You take for

* In the *Berlin. Klin. Wochenschrift*, July 6 and 13, *vide* *London Medical Record*, Aug. 12, the case of Carius above referred to is given in full, as well as some additional observations relating to this curious affection.—Ed. J. H. G.

this purpose a piece of ordinary india-rubber tubing, such as is used for gas-lamps, about six feet long; you next round one end with a scissors, and, if necessary, cut two holes at a short distance from the end. This tube possesses quite sufficient rigidity to be passed without difficulty into the stomach. To the outer end you now fit a funnel, into which you can pour either water or a solution of soda, etc., according to circumstances. If you want to remove the contents of the stomach, you must sink the outer end of the tube to a level with the pubis, or even lower; then let the patient make a short but forcible contraction of the abdominal walls. By this means the tube is filled to its highest point with the fluid contents of the stomach, and becomes a siphon, the liquid continuing to flow until there is no more, or till the tube has got stopped up. This last seldom occurs if the tube is of a moderate calibre. Should it, however, happen, or should the abdominal pressure be insufficient to fill the tube in the first instance, or the patient be insensible, or any similar difficulty arise, it can, in general, be readily overcome by fitting a common clyster syringe to the end of the tube, one stroke of the piston of which is generally sufficient to remove the difficulty, and the fluid continues to flow after the removal of the syringe. This method is evidently instantaneously available, provided that we can find a gas india-rubber tube; and it has another great advantage, viz., that with it any mechanical injury to the soft parts is impossible.*

In cases where the œsophagus is almost impervious from stricture, compression, or any other cause, I am in the habit of using very thin gum-elastic tubing, made especially for this purpose, within which a very thin piece of whalebone, like the stilet of a catheter, is introduced, in order to give it the necessary rigidity. The whalebone can be withdrawn without difficulty once the tube is passed. Since I have adopted this method, it is only during the first or second introduction of the tube that I have experienced any difficulty arising from the discomfort the operation causes to the patient.—*Dr. Ewald, Charité Hospital, Berlin, in Irish Hospital Gazette.*

GLEANINGS FROM OUR EXCHANGES.

TUMOR OF THE BREAST IN A MAN AGED SIXTY-EIGHT.—At the Surgical Society of Paris, a man aged sixty-eight was lately exhibited by M. Demarquay, from whom he had removed a tumor of the breast. The tumor was voluminous and composed of three cysts: the largest was of a bluish tinge, and threatened to burst. Complete absence of axillary glands. It first appeared three years ago. M. Demarquay stated that he had seen only two cases of cancer of the breast in men; the progress of the disease was rapid, and the axillary glands were affected. In the case under notice there is nothing of the kind; but a cyst was on the point of bursting, and an operation was, in consequence, considered advisable. Extirpation was performed without involving the pectoral aponeurosis; histological examination of the tumors proved the presence of cysts developed in the galactophorous tubes. M. Tillaux stated that, while he acknowledged the rarity of cancer of the breast in men, he had operated only a month ago on a man who had a tumor of the breast about the size of a large pea, which had attained its present volume in one year, and was accompanied by an abnormal development of the glands in the axilla. Microscopical examination proved the existence of cancer. The writer

of this note saw a case some four or five years ago in M. Maisonneuve's ward at the Hôtel-Dieu. The tumor was about the size of a Mandarin orange, which was removed by means of his caustic "flèches." The patient was a priest, aged about forty-five, and the tumor was rapid in its development; notwithstanding this, M. Maisonneuve was disposed to look upon the tumor as non-malignant, but microscopical examination proved it to be a cancerous tumor. This eminent surgeon stated that in all his practice, extending over forty years, this was only the second case he had met with.—*Paris Medical Record, July 1, 1874.*

ALCOHOLIC STRENGTH OF THE VARIOUS BITTERS.—Mr. Henry Vaughan, State Assayer of Rhode Island, gives the following results of a chemical examination of the more important "bitters" found in the market:

	Per cent.
Hoßtetter's Stomach Bitters	43.20
Baker's Stomach Bitters	40.57
Drake's Plantation Bitters	30.24
Sol. Frank's Panacea Bitters	37.20
Mishler's Herb Bitters	36.80
Dr. R. F. Hibbaw's Wild Cherry Bitters	35.89
Rush's Bitters "for the Stomach's Sake"	34.30
Dr. Fisch's Bitters	32.16
Baker's Orange Grove Bitters	25.70
Speer's Standard Wine Bitters	25.49
Traveller's Peruvian Bitters	22.40
Dr. Clarke's Sherry Wine Bitters	22.40
California Wine Bitters	18.20
Dr. Wheeler's Tonic Sherry Wine Bitters	14.66
Atwood's Quinine Tonic Bitters	40.10
Dr. Holmes's Golden Seal Bitters	34.24
Dr. Job Sweet's Strengthening Bitters	31.41
Webber's Strengthening Bitters	26.87
Flint's Quaker Bitters	22.99
Restorative Bitters	20.54
Luther's Temperance Bitters	16.68
Richardson's Bitters	59.14
Armington's Bitters	33.26
Davis's Bitters	30.50
Colton's Nervine Bitters	29.73
Dr. Warren's Bilious Bitters	29.60
Hartshorne's Bitters	27.35
Atwood's Jaundice Bitters	25.60
Puritan Bitters	25.60
Dr. Langley's Bitters	24.41
Dr. Hoofland's German Bitters	20.85
Oxygenated Bitters	19.28
Walker's Vinegar Bitters	7.50
Dr. Pierce's Bitters	6.36

—*The Laboratory.*

DETERMINATION OF THE SEX IN UTERO (*The Medical Examiner*, August 15, 1874).—Drs. Strong and Steele make the following deductions from their joint observations of one hundred cases:

1. In the majority of cases male foetal hearts are slower than female.
2. One hundred and thirty-two foetal pulsations per minute is the average which constitutes a dividing line between the sexes. Below this, sixty-eight and four-sevenths per cent. are males, twenty per cent. are females, eleven and three-sevenths per cent. are doubtful. Above this, fifty-three and one-third per cent. are females, twenty-six and two-thirds per cent. are males, twenty per cent. doubtful.
3. The most accurate observations are made during the last four weeks of gestation.
4. The rapidity of the heart's action is increased in proportion to the feebleness of the foetus.
5. Calcareous or fatty degeneration of the placenta renders the pulsations feeble and irregular.
6. In some cases it would be possible to diagnose

* NOTE BY TRANSLATOR.—In the *British Medical Journal* of February 24, 1874, p. 205, will be found a description of a very similar apparatus for washing out the stomach, invented by L. H. Tossill, M.B.

diseased conditions of the placenta from careful observation of the foetal heart.

In conclusion, it may be generally stated that an opinion as to the sex of the child, founded on the rate of the foetal pulse, is of little more value than a guess, while the presentation, generally, and the exact position, possibly, may be accurately determined.

FATTY GROWTH IN THE CORPUS CALLOSUM (*British Medical Journal*, July 18, 1874).—At an autopsy on a case of tubercular meningitis, Dr. Joseph Coats discovered a peculiar pathological condition which he describes as follows. On the upper surface of the corpus callosum there was an elongated yellow structure, occupying its entire length and in the middle line. It was of nearly the same bulk in every part, averaging about five-sixteenths of an inch in breadth, and about three-sixteenths in thickness. It had the appearance of a narrow ridge on the corpus callosum, and seemed to be involved in the pia mater, a layer of which covered its surface, and another separated it from the nervous tissue of the corpus callosum beneath. This growth was found, on microscopic examination, to be composed of typical adipose tissue, the large fat-cells having exactly the normal appearance.

TREATMENT OF CHRONIC NASAL CATARRH (*The American Medical Journal*, August, 1874).—Dr. John W. Thraillkill describes an instrument devised by himself for making topical applications of powdered substances to the nasal passages. It consists of a bent glass tube connected by a rubber tube with a glass mouth-piece. The powder is put into the glass tube, which is inserted into the nose to the distance of half an inch or more; the patient then puts the mouth-piece into his mouth, and blows the powder with a quick, strong blast into the nose. This plan has many advantages: the medicament is not drawn back into the pharynx, as when it is snuffed in, and it is distributed much more equally through the nasal cavities. A powder consisting of one drachm of calomel to two drachms of sugar of milk has been found highly efficacious in chronic cases of nasal catarrh which had lasted for years and had resisted treatment by douches, washes, etc.

TRAUMATIC TETANUS—MORPHIA—RECOVERY (*The Nashville Journal of Medicine and Surgery*, August, 1874).—Dr. R. D. Winsett reports the case of a cavalry officer, æt. 24, who received a wound in the glutei muscles, which was followed in six or seven days by marked tetanic symptoms, with spasms, complete trismus, and opisthotonos. He was ordered every three hours a pill containing one grain each of powdered camphor and assafoetida, and a half-grain each of extract of belladonna and sulphate of morphia. In addition, he was given a grain of sulphate of morphia every hour, with large quantities of gruel and milk-punch. He continued without much change for eight days, the same treatment being persevered in,—sixteen grains of morphia being given daily. At the end of that time he began to improve, and in a few weeks entirely recovered.

CASE OF OCCLUSION OF THE GALL-BLADDER (*British Medical Journal*, July 18, 1874).—Mr. Corrie Jackson, while making an autopsy on a case of apoplexy, discovered that the liver was enormously enlarged, to the weight of nearly ten pounds; the structure was tolerably healthy. The gall-bladder was filled with calculi, to the number of two hundred and thirty-seven; the aggregate weight being 420 grains. The calculi were an almost exact representation, in size, appearance, and color, of grains of Indian corn, rounded on their outer surfaces next the gall-bladder, and flattened internally by their compression and packing. There was

no form of jaundice. The ductus communis choledochus was patent; and the circulation of bile in the gall-bladder could only have been carried on in the interstices of the outer surfaces of the calculi. There was no history of any dyspepsia, constipation, or hemorrhoids.

MAMMARY ABSCESS IN INFANTS (*British Medical Journal*, August 8, 1874).—From a number of communications received, it seems that mammary abscess is of very frequent occurrence in children otherwise entirely healthy. It is sometimes due to improper irritation of the nipple by the nurse, but oftener to the retention of a secretion of thin milk, which takes place in the breasts of male as well as female children, and, when prevented from escaping, sets up inflammation and suppuration.

MISCELLANY.

MISSIONARY MEDICINE AND THE CHINESE.—Dr. Dudgeon, in the annual report of the Peking Hospital for 1873 to the London Missionary Society, states that during the past year the entire number of patients prescribed for was 18,300. The influence of the hospital is said to be yearly extending, and its connection with the higher and official classes steadily increasing. A lectureship on anatomy and physiology in connection with the present college has, moreover, brought Dr. Dudgeon into close contact, professionally and otherwise, with the highest officials of the government.

A YOUNG Japanese, Susum Sato by name, has obtained, after a highly creditable examination, the degree of M.D., Berlin. His graduation thesis, on the subject of Infantile Diarrhœa, is said to have been exceptionally good. The rapidity and ease with which Mongolians devoted to study acquire a knowledge of foreign languages are remarkable.

DR. GEORGE M. BEARD, of New York, has issued an elaborate circular, asking for information in regard to cases of hay-fever. Those who are able and willing to aid him will please apply by letter for copies.

NOTES AND QUERIES.

THE ADAMS COUNTY MEDICAL ASSOCIATION.

This Association held its annual meeting on Tuesday, Sept. 1, and elected the following gentlemen as officers for the present year:

President, Dr. J. W. C. O'Neal.

First Vice-President, Dr. I. W. Pierson.

Second Vice-President, Dr. I. L. Baehr.

Recording Secretary, Dr. Charles Horner.

Corresponding Secretary, Dr. William J. McClure.

Treasurer, Dr. E. W. Mumma.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY, FROM SEPTEMBER 1 TO SEPTEMBER 7, 1874, INCLUSIVE.

HARTSUFF, A., ASSISTANT-SURGEON.—Assigned to duty as Post-Surgeon at Fort Laramie, Wyoming Territory. S. O. 126, Department of the Platte, August 29, 1874.

MONROE, F. LEB., ASSISTANT-SURGEON.—Granted leave of absence for one month, provided he furnishes a suitable substitute during his absence. S. O. 139, Department of the South, August 29, 1874.

SATURDAY, SEPTEMBER 19, 1874.

ORIGINAL COMMUNICATIONS.

A CASE OF CHRONIC PERICARDITIS, WITH TUBERCULOUS PLEURISY.

BY WILLIAM PEPPER, M.D.,

Professor of Clinical Medicine in the University of Pennsylvania.

A BRIEF and partial report of the following case was published in an article on the treatment of Pleural Effusions, which appeared in the number of this journal for July 11, 1874; but, as the case has since terminated, and the results have seemed of unusual clinical interest, the entire report is now given:

Mr. B., æt. 26, of well-marked strumous diathesis, had a grave attack of diphtheria in the winter of 1872-3, and had never recovered his previous health, although he was under no medical treatment. In March, 1874, he consulted Dr. Yarrow, his family physician, who found him suffering with extreme dyspnœa, connected with large double pleural effusion. The origin and development of this had been entirely latent, and the symptoms had been gradually increasing. The dyspnœa was constant and alarming, attended with violent play of the alæ nasi; there was also extreme pallor of the surface.

Careful internal treatment caused a reduction in the amount of the effusion on the left side, but influenced that on the right side very slightly. I saw the case with Dr. Yarrow in May, with a view of determining the propriety of paracentesis. The evidences of pleural effusion on both sides were very distinct. On the right side the line of dulness reached to the third interspace, in the sitting posture, and was much influenced by change of position. On the left side the effusion came up to the fourth interspace. The entire thorax was distended; the respiratory movements were abrupt and jerking, and consisted mainly of elevation and depression, with some expansion of the apices. They varied from twenty-eight to thirty-six in a minute. The respiratory murmur at both apices was somewhat exaggerated, but otherwise healthy: the percussion-resonance was pseudo-tympanic. The impulse of the heart was very feebly and indistinctly felt over a larger area than normal, and somewhat higher than its normal position. On auscultation, the cardiac sounds were distant, feeble, and muffled, but without any valvular murmur. There was no thrill, nor any retraction of the intercostal tissues over the apex. The pulse was feeble, frequent, varying from 108 to 124, and irregular. There was some hectic irritation, but not enough to countenance the idea of the effusion being purulent. There was marked fulness of the large veins in the neck. There was a good deal of cough, with scanty mucous sputa. The abdomen was tumid; the liver was pushed downwards, and was very painful on pressure. There was but moderate enlargement of the spleen, and none of any of the lymphatic glands. The urine was free from albumen. The appetite was poor, and the action of the bowels irregular.

The diagnosis determined upon was that of tuberculous pleurisy with extensive serous effusion. For a short time the attempt to afford relief by internal treatment was continued, in consequence of the unfavorable nature of the case. This treatment consisted of a milk diet, quinia, iodide of potassium, and digitalis. It was soon evident that no great relief could be hoped for.

He took milk in large quantities, but the stomach grew irritable, and diarrhœa with mucoid stools set in.

After careful consultation, we decided, on June 9, to puncture the right thorax in the sixth intercostal space, in the line of the anterior border of the axilla. Dieulafoy's aspirator was employed, and seventy-five fluid-ounces of straw-colored serum were withdrawn. The closing portion of the operation was very painful,—evidently in consequence of the powerful traction upon the expanding lung. There was still more effusion, but the flow was interrupted by the lung coming in contact with the canula. Immediately after the operation the patient was seized with violent paroxysmal cough, which caused so much pain as to require repeated doses of opium. There was immediate relief of respiration, with a return of respiratory murmur over a part of the area from which it had previously been absent. About six hours later, a very alarming syncopal attack occurred, from which he was roused only by repeated and large doses of stimulants. During the night copious sero-albuminous expectoration commenced, and in the course of the next twenty-four hours almost a pint was discharged. This was compared by the family to the fluid which had been evacuated from the chest, consisting of a clear, serous fluid, in which a large muco-fibrinous coagulum formed. There seemed no real purulent element with it. This copious expectoration continued for about forty-eight hours, becoming mixed with a considerable amount of blood. After this it diminished, and the blood gradually disappeared.

Physical examination showed marked diminution of dulness on right side, with a return of respiratory murmur, mixed with coarse crackling and grating friction-sounds. There seemed to be some reduction in effusion on left side also, but no change could be detected in the action of the heart. It still remained irregular and feeble, with obscure sounds, free from valvular murmur. It was impossible to determine the area of cardiac dulness, owing to the double pleural effusion. The patient experienced a great deal of relief for several days, when again severe dyspnœa gradually set in.

Coarse friction-sounds now appeared over the anterior surface of the left chest, especially marked about the border of the præcordia. Occasionally this friction-sound was of cardiac rhythm, and was detected during suspended breathing. Its position indicated that it was produced by the rubbing of the heart against the concavity of the left lung.

The abdomen continued tumid, with great tenderness over the upper portion. The liver returned in a slight degree only towards its normal position. The irritability of the stomach continued, milk being the only food taken in any quantity. Diarrhœa persisted, requiring the use of opiate suppositories; and œdema of the legs appeared, and rapidly increased. Cough continued, though less troublesome than immediately after the operation. The sputa were purulent, and occasionally blood-stained. About two weeks after the operation he was suddenly seized with a profuse hæmoptysis, to the amount of not less than thirty fluid-ounces in the course of twelve hours. For several days expectoration was quite copious and largely composed of blood.

On June 25 another syncopal attack occurred, attended with prolonged failure of the heart's action. He reacted slowly and imperfectly, and afterwards began to sink gradually, and died June 30.

At the post-mortem examination (twenty-four hours after death), both pleural sacs contained a large amount of clear serous effusion. The surface of both pleuræ was thickly studded with gray milary tubercles, with scarcely any formation of false membranes. The lungs were

not adherent, but were both compressed and dense, and forced upwards and backwards by the effusion. On section of the right lung, numerous spots of apoplectic infarction were found. These seemed comparatively recent, as no changes of color had occurred in the effused blood. There were but very few and small patches of this kind in the left lung. There were a few milary tubercles scattered through the tissue of both lungs. There was no trace left to mark the point of puncture.

There was a small amount of serum in the peritoneal cavity, but no signs of inflammation or of tuberculous formation on the peritoneum. The *liver* was enlarged, deeply congested (nutmeg), and was pushed downwards so that at least half of its bulk lay below the margin of the ribs. The *spleen* was nearly threefold its normal size, its pulp firm, and apparently normal, without any tuberculous formations. The *kidneys* were congested, but otherwise healthy.

The *heart* was pressed backwards by the pleural effusion. The outside of the pericardial sac was roughened, and studded with milary granulations. On cutting into the pericardial sac, its cavity was found obliterated, the heart being imbedded in a layer of old organized lymph, half an inch in thickness, arranged in coarse meshes, infiltrated with sero-purulent fluid. The layers of the pericardium were thickened and vascular, and the lesion was evidently one of long duration. The heart was somewhat enlarged; the valves were healthy, but the muscular structure showed evidences of fatty degeneration.

The case here reported seems to present interesting questions as to its diagnosis, pathology, and treatment. The recognition of the pleural effusion was as simple as possible, but it was not so easy to determine its cause. The extreme pallor and prostration which marked the case from the beginning have been already noted; and so unusual were they as strongly to suggest the existence of some serious cachexia. The urine was entirely normal; and there had been no symptom to attract attention to the kidneys as being at fault. The idea of leukæmia was entertained and dismissed on account of the absence of any marked splenic or lymphatic enlargement, and from the early appearance of double hydrothorax without any other form of dropsy. The idea of the effusion depending on tuberculous disease of the pleura seemed the most plausible, on account of the latent and painless origin, the bilateral character of the effusion, the existence of hectic irritation, though of but slight degree, the strumous diathesis of the patient, and the absence of symptoms of any other cachexia. The absence of hæmoptysis or of any physical sign of tuberculous disease of the lung-tissue was not surprising, since in some cases of serous tuberculosis the viscera escape almost entirely. The peculiar absence of cardiac impulse, and the feeble, distant, and irregular character of the sounds, were observed and commented upon, but, in the absence of any other sign of valvular disease or of pericarditis, were attributed to the pressure of the fluid in the two pleural sacs.

It will be seen, however, that, although the diagnosis was correct so far as it went, the remarkable chronic pericarditis escaped recognition entirely. The characters of this latter lesion indicated that it was of long standing; and my opinion is that it was the initial condition, and possibly dated back to

the attack of diphtheria. Of late years inflammation of the membranes of the heart (especially of the endocardium) associated with granular degeneration of the muscular fibre has been quite frequently observed as a complication of this affection. If the disease had this origin in the present case, the protracted irritation due to the unhealthy suppurative inflammation developed the pre-existing tuberculosis diathesis and led to the formation of milary tubercles on the pleura. It is also seen that the extensive effusion recognized a double cause, the venous stasis due to the condition of the heart, and the disease of the pleuræ themselves. The occurrence of pulmonary apoplexy was entirely dependent upon the cardiac disease, although, as will be hereafter remarked, it may have been directly connected with the operation of paracentesis.

In regard to the treatment, the hopeless nature of the case was easily recognized from an early period. Still, it was highly interesting to observe, even in the presence of such extreme cardiac embarrassment, the marked action of digitalis. Beginning with ten drops of the tincture three times a day, it was increased to fifteen drops every four hours. The effect of this was to reduce the pulse from 110 or 120 to 96, to render it more regular, to increase the flow of urine, and to diminish the effusion in the left chest. Unfortunately, with the advance of the disease, digitalis lost the power of controlling the symptoms.

In the performance of paracentesis no difficulty was experienced, except from the severe pain which attended the latter part of the operation; but I would call especial attention to the phenomena which followed,—the occurrence of hæmoptysis and of sero-albuminous expectoration. It was evident, from the painful sense of the traction exerted by the aspirator after a portion of the effusion had been withdrawn, that the lung was unable to expand freely to replace it. It is easy to imagine the effect of this powerful traction upon a lung whose veins were engorged from cardiac disease, and whose vesicular tissue had been so long compressed by effusion as to render it to a great extent unable to expand. The first result would be to induce increased effusion of serum from the vessels of the bronchial mucous membrane, constituting the peculiar sero-albuminous expectoration described; and if the action were powerful enough, it might further cause hemorrhage either from the bronchi, leading to hæmoptysis, or in the vesicular and interstitial tissue, producing apoplectic infarction. It is true that in this case the condition of the heart must have had much to do with the production of these latter phenomena, but the facts that hæmoptysis appeared for the first time immediately after the performance of paracentesis, and that the patches of pulmonary apoplexy were evidently of recent occurrence, show conclusively that this operation was directly connected with them. It is, I think, highly probable that all cases of this comparatively rare form of expectoration after paracentesis, called by the French writers "sero-albuminous," are due to the excessive traction upon the tissue of a lung whose vesicular structure is unable to expand; an

engorgement of the blood-vessels is induced, which is partly relieved by copious effusion of serum from the bronchial mucous membrane. It remains only to notice the syncopal attacks, which were similar, although unusually severe, to those which occur in some uncomplicated cases of hydrothorax. In fact, it has been frequently observed that sudden death may occur most unexpectedly from the interference with the heart's action caused by an excessive effusion, even on one side. It will be readily understood how liable our patient must have been to such alarming attacks, and it is rather to be wondered at that sudden death had not occurred. It is difficult to explain the connection of the operation with the syncopal attack which took place six hours subsequently. Unless a curious coincidence, it was probably due to the excitement and fatigue attendant upon the operation itself.

The liability to such seizures was clearly shown by the occurrence a few days afterwards of an even more alarming attack, despite the relief afforded by the withdrawal of so large a quantity of serum. The operation itself was quite successful, and seems to have been clearly indicated, although, even without a knowledge of the latent pericarditis, it was impossible to hope that it would afford more than temporary relief.

INVERSION OF THE UTERUS FROM SHORT CORD.

BY D. F. WOODS, M.D.

INVERSION of the uterus is, fortunately, a rare accident. On account of its infrequency the following case is of value, and its history may not prove uninteresting to the readers of the *Medical Times*:

About a year ago I attended Mrs. B. in her first confinement. When I arrived at her house, I found her in the first stage of labor. There was nothing worthy of note in this dilating stage. Soon after the commencement of the second stage, the patient complained of a dragging or tearing pain in the region of the umbilicus, which pain was greatly intensified during the contractions of the uterus. Each bearing-down effort was preceded and accompanied by a feeling of dread, and as labor progressed the sensation of dragging or tearing pain became more and more agonizing. The woman described it as "a feeling as if her whole insides were tearing to pieces."

The child presented in the second position (right occipito-anterior) of the vertex. This dragging or tearing sensation lasted through the whole of the second stage, which was prolonged about eight hours.

As soon as the head was delivered, and I could reach the cord, I cut it, applying the ligature some time after to the child. The cutting of the cord did not, however, arrest the already partially-inverted uterus, for a heavy pain stopped by the contraction of the diaphragm brought down the whole contents,—the uterus completely inverted, with its placenta firmly adherent at its fundus. Hemorrhage occurred in great profusion from the inverted organ, which seemed to me to extend to the patient's knees.

With considerable effort I tore the placenta from its firm plastic adhesions, and afterwards endeavored to restore the uterus to its normal position. This at first

was no easy matter, as I found the more I attempted to restore it, the more contracted its mouth became.

Finally I resorted to the following method. With the hips of my patient considerably elevated, the thumbs of both hands applied to the fundus, by degrees I was able to overcome the resistance, and make sufficient indentation to push the fundus with my right hand through the os uteri, which gradually relaxed as it had contracted. By degrees I restored the organ to its normal position in the abdomen. When this was accomplished, my right hand was introduced into the cavity of the uterus, where, holding it, I ordered three drachms of wine of ergot to be given, at the same time making slight friction over the abdomen with the other hand. I soon felt the uterus contract firmly upon my introduced hand, which I gradually withdrew.

The hemorrhage, which to this moment was very profuse, ceased. I applied a bandage with a firm compress to hold the uterus contracted, gave a large anodyne, and ordered two drachms of the wine of ergot to be continued every half-hour until four doses were given, and after that gradually discontinued. The ergot was kept up for ten days, in doses of a drachm every three hours. My patient was considerably exhausted from the excessive hemorrhage, and the next day complained of considerable soreness over the abdomen. Independent of these, she gradually recovered without any further serious untoward symptoms.

The child (a female) was slightly asphyxiated at birth, but soon recovered under the simple treatment of alternate cold and hot douche, and she is now a large child, about a year old.

An examination of the placenta showed signs of former inflammation at its uterine connections, evinced by an excess of what appeared to be fibrinous coagula of considerable hardness. The cord was bound round in a ball with plastic exudation, holding it firmly and moulding it closely to the amniotic layer at the fundus where attachment took place.

The whole length of the cord was not six inches. The woman had a number of falls at various intervals during her pregnancy. At one time, the pavement being slippery, she fell on her door-step, striking her stomach. The injury at no time gave her severe annoyance, except muscular soreness the next day,—not sufficient to call in a physician.

Since the occurrence of the above, I have attended this same patient in her second confinement; the interval being a few days over thirteen months. This last is a large, well-formed male child, and presented in the left oblique of vertex (left occipito-anterior). The mother had a quick delivery, and no difficulty whatever. Both mother and child are doing well.

A CASE OF RUPTURE OF THE BICEPS.

BY J. BROOKE,

Assistant-Surgeon U.S.A.

THE case of rupture of the biceps reported in a recent number of the *Medical Times* recalls one which I observed over five years since.

A discharged soldier, who was an applicant for admission to the Asylum for Disabled Volunteers, presented (I forget in which arm) a deep depression almost in the middle of the belly of the biceps, the muscle having evidently been ruptured and the torn ends remaining separated by an interval of at

least an inch. There seemed to be no muscular connection between the torn ends. The man stated that while one of a party carrying a small house or sentry-box he suddenly felt something give way, and the arm became comparatively powerless. The accident occurred a considerable time before I saw him,—I think over a year,—and the power of flexing the fore-arm was still greatly impaired.

SITKA, ALASKA, August 3, 1874.

BELLADONNA IN SPASMODIC ASTHMA.

BY GEORGE G. WOOD, M.D.

THE communication in the *Philadelphia Medical Times* for August 29, on "Chloral Hydrate and Bromide of Potassium in Spasmodic Asthma," by Dr. Julio J. Lamadrid, has led me to offer my experience with belladonna in the same disease. Being located in a neighborhood where spasmodic asthma abounds plentifully in the autumn, I have had a fine opportunity for testing the value of the various remedies recommended for its treatment. Of all tried, which includes the hydrate of chloral and bromide of potassium, of whose use in spasmodic asthma in this country Dr. Lamadrid claims priority, I greatly prefer belladonna. It is only when belladonna, after a good trial, proves to be contraindicated, for reasons I shall hereafter state, that I make use of chloral; then I consider it the next most available remedy. Bromide of potassium has failed to produce much effect in the cases where I have tried it, either in conjunction with chloral or alone.

Belladonna, by actual experiments on animals, has been found to dilate the bronchial tubes, and keep them dilated so long as the animal remains under the influence of the drug. And, further, this dilatation persists notwithstanding irritants be employed for the purpose of making them contract. These experiments very satisfactorily account for the medicinal action of belladonna in the treatment of spasmodic asthma.

The pathology of the disease teaches us "that it is owing to a spasmodic constriction of the smaller bronchial tubes, by tonic contraction of their involuntary muscular fibres."

Belladonna, then, acts simply by relieving this constriction of the bronchial tubes.

To get the good effects of belladonna in asthma, it must be given in heroic doses. I usually employ the tincture of the United States Pharmacopœia, in doses ranging from twenty to sixty drops. The strength of the tincture differs so much, as commonly kept in the shops, that the size of the dose must be lost sight of, and the quantity given be regulated by the effect produced. It may be given during the paroxysm with great advantage, but it acts best when given before the attack commences. For example, if the patient has nocturnal attacks coming on after midnight, as is usual, give him a dose just before going to bed, and repeat it if necessary to produce sound sleep. He fails to awake at the usual time for the attack to commence, and sleeps on, awakening in the morning very much refreshed

and strengthened. This treatment may be repeated night after night, until sufficient time has been had to remove the tendency of the disease to return, either by changing his location or adopting other requisite treatment, as the case may call for. I could relate several cases to prove the above statements, but will have to omit them for want of space.

Sometimes, but not often, belladonna produces dryness of the fauces, and delirium. These are indications which show that it should be discontinued and hydrate of chloral should be employed in its stead. It may be used on the same principles as belladonna to produce sleep and thus ward off attacks. For the past two years I have been treating spasmodic asthma on these principles, and with most satisfactory results; yet I do not claim any originality in their conception: they are simply hints gathered from many sources, their value being well proven, to my mind, by experience.

MUNCY, PENNA., September 4, 1874.

TRANSLATIONS.

AMPUTATION OF PART OF THE COCCYX IN AMUSSAT'S OPERATION FOR IMPERFORATE RECTUM.—In a communication read before the Société de Chirurgie recently (*Bulletin de la Société de Chirurgie de Paris*), M. Verneuil recommends resection of the coccyx in order to facilitate the establishment of a perineal anus in cases of imperforate rectum. By this means more room is given in which to operate, the ends of the operation are more easily attained, and the after-results are more satisfactory, than in the ordinary procedure, without adding to it any corresponding danger.

He condemns the practice of treating cases of imperforation of the anus by thrusting a trocar in the direction of the supposed termination of the bowel, as being uncertain, inefficient, and dangerous, and recommends the median incision in all cases, with removal of part of the coccyx when necessary. He became convinced of the value of this as early as 1852, by the autopsy of an infant upon whom Littré's operation had been ineffectually performed. In this case the anus opened into a cul-de-sac two centimetres in depth. In the dissection the occluded end of the rectum was found one centimetre above this, where it might have been reached by the ordinary Amussat's operation, although with some difficulty: this, however, could have been obviated by a resection of the coccyx, which brought the distended rectal pouch well into view.

Carrying this principle into practice, he has performed the operation six times, and the details of these cases occupy the greater part of his paper. In these cases—five male and one female—he obtained highly satisfactory results, the credit of which he gives to this modification, which he was obliged to resort to in five out of the six, and affirms that without this help in at least two of them he would have been obliged to relinquish the operation. Four of the children were born at term, one at eight months and one week, the other at eight and a half months. None of them showed any other vice of conformation. In four the anus was well defined, but terminated in a cul-de-sac averaging 12 millimetres in depth, and the intergluteal crease was well marked. In the other two the perineum was rounded and projecting; in one the anus was represented by a tubercle without any opening.

Regarding those simple cases where the occlusion consists merely of a membranous wall, he states that he

has never met with any of them. He has also sought in vain for the fibrous cord which is said to replace the obliterated portion of the intestine and act as a guide to the occlusion. It has been pointed out in dissections, but he found that when operating, if it existed, it was indistinguishable.

He claims that a resection of the coccyx shortens the operation and thus reduces the amount of hemorrhage. Besides exposing the intestine more readily, this operation facilitates materially the close approximation of the mucous and cutaneous edges by suture, thus making a natural muco-cutaneous outlet, and preventing the dangers of infiltration and abscess, or subsequent contraction.

Although four of the cases died subsequently, only one of them showed any symptoms of local trouble after the operation. This one suffered from secondary hemorrhage, orchitis, extensive erysipelas, followed by diarrhoea with prolapse of the bowel (which was reduced spontaneously), and finally died at the end of five weeks. In all of the cases the artificial anus performed its function in a satisfactory manner from first to last. In one case some contraction was noticed, which was remedied by a slight incision; but in none was there any abscess, severe inflammation, or peritonitis.

One of the successful cases was operated upon nine years ago, and the present condition is completely satisfactory. The abridgment of the coccyx is not noticeable, and he shows no material or functional trace of his malformation. In another case of four months' standing the success may be considered as assured. In this case, some months after the operation a urethro-anal fistule was discovered, which was evidently due to the persistence of a communication which is sometimes found in these cases as a cord leading from the bowel to the membranous portion of the urethra.

The paper ends with the following conclusions:

1. Perineal enterotomy is the operation of election in cases of ano-rectal imperforation.
2. It should be performed as soon as possible by the operation of Amussat, which is the least dangerous at the time, and more efficient ultimately.
3. It presents undeniable difficulties, connected with the discovery of the bowel and the fixation of it to the borders of the cutaneous surface.
4. The partial resection of about one centimetre of the coccyx, on an average, diminishes these difficulties considerably.
5. Without destroying much tissue, it allows a great enlargement of the field of operation, enables the operator to reach the rectum when high up, and to attach it to the skin without much traction, or requiring dangerous dissecting from antero-superior adhesions in order to make the bowel movable.
6. It saves us from plunging blindly into the pelvis, and protects the peritoneal cul-de-sac and urinary passages from accidental wounding.
7. It shortens the operation materially.
8. It is easy of execution, and seems, thus far, to be without dangers of its own.
9. The excision of the coccyx is not always necessary, but if after some fruitless attempts the intestine is not found in the wound, or, when found, does not come down well, it should be resorted to without hesitation.
10. If after the said resection the intestine is not *speedily* found, the perineum should be abandoned and the lumbar or iliac operation performed.
11. Perineal enterotomy, although carefully performed and definitively successful, may be followed by a peculiar variety of ano-urethral fistule due to the persistence of an embryonic structure.

In the discussion of this paper at the succeeding séance, M. Verneuil stated that by this means the intestine might be reached at a depth of three centimetres.

F. W.

TWO CASES OF MALIGNANT PUSTULE (Dr. B. Fränkel: *Berliner Klin. Wochenschrift*, No. 22, 1874).—The first patient was a mechanic, aged 42, employed in the shops of a railroad, and was admitted into the Augusta Hospital on the 31st of January, on account of an inflammatory swelling of the neck. He was seen by Dr. F. on the 1st of February, who then found an insignificant-looking crust near the chin and just above the edge of the under jaw, which was surrounded by a swollen area of a bright-red color. The appearance presented was very much that of an acne pustule which had been scratched and irritated. The patient stated that he had noticed a few days previously, at the affected point, a little pimple, which annoyed him by itching; that he had scratched and irritated it; that, in consequence of this, the redness and swelling had increased. The redness and swelling at this time had extended from the neighborhood of the crust over the entire anterior portion of the neck, and on the right side had passed over the clavicle and ended in a sharp line over the deltoid muscle and the first intercostal space. The redness was in all respects like that seen in erysipelas; the swollen part was doughy, with no sense of fluctuation, and in it at certain points could be felt hard bodies, which were, apparently, swollen lymphatic glands. These hard spots were especially noticeable beneath the sterno-cleido-mastoid muscle. The patient was in full possession of his faculties, and complained of nothing except pain in the inflamed portion of his neck and upon moving his head. The temperature was 39.3°. The appearance of the patient gave rise to a suspicion that the wound was due to infection; but the most careful inquiries were all met with a negative answer. The following day the temperature rose to 39.7°; the redness extended itself farther outward and downward on the right side, the patient complained of thirst and difficulty in swallowing, and the mucous membrane of the pharynx was found to be uniformly livid and swollen.

On the 3d of the month the evening temperature was 37°, and the redness and swelling became a little less marked. The patient, however, showed symptoms of asphyxia, became cyanotic, and died.

The autopsy was made on the 5th. The entire connective tissue of the neck was soaked in reddish serum. This œdema followed the trachea into the mediastinum, and could be seen along the bronchial tubes and over the pericardium. It followed, too, the œsophagus, and was seen upon the mesentery. Wherever this œdema was seen, the lymphatic glands were found to be swollen, in some cases to the size of a walnut, and they were so full of dark blood that they presented a striking resemblance to clots of that fluid.

After the diagnosis had been established by the post-mortem appearances, an attempt was made to clear up the etiology of the affection, and it was found that the deceased had been employed in the shop in sorting the hair taken from the cushions of old railroad-cars. New hair, which had been previously disinfected by boiling, was mixed with the old, and it is a question, of course, as to which contained the virus whence the infection came. The infected spot on the chin may have been due to a direct contact of the hair with that part, or, as is more probable, to the inoculation of virus from the fingers by scratching.

The second case occurred in a nurse, aged 36, who up to the time of this attack had been a healthy man. He sewed up the wounds in the body of the former patient which were made at the post-mortem, and seven days later, on the 12th of February, he first felt that he was ill, and on the 13th he was admitted into the hospital. Dr. F. saw him on the 14th and 15th of the same month, and then noticed some small fissures of the skin between the fingers of the left hand, together with

red streaks along the course of the lymphatics in the arm, enlargement of the axillary glands of the same side, and redness in the axilla of the opposite side. On the 15th, asphyxia and cyanosis came on, and on the afternoon of the same day he died, in full possession of his faculties. The symptoms were very similar to those of the former case, the temperature rising to 40.6° on the evening of the 13th, and falling on the 15th to 36°. The thirst, too, was intense, and during the existence of the cyanosis and asphyxia the sounds of the heart were heard with difficulty. The origin of the infection in this case was the body of the previous patient, and the infection must have taken place on the 5th or 6th of the month, so that there was a period of incubation of either six or seven days. The usual localization of the contagion of malignant pustule was not found in this case. There was no œdema nor carbuncle at the point at which the infection took place. If the redness along the lymphatics of the arm had not been seen, there would have been no means of finding out by what channel the infection had taken place, and the case might have been looked upon as one not due to infection from without. The local absorption, however, was most distinctly manifested by the inflammation of the lymphatic vessels, even if carbuncle and œdema were absent.

W. A.

DEVELOPMENT OF CANCER OF THE KIDNEY FROM THE EPITHELIUM OF THE RENAL TUBULES.—Pereverseff (*Centralblatt für Med. Wissenschaften*) reports a case of cancer of the kidney, in which the parenchyma of the right kidney, while keeping its normal form and size, was infiltrated by cancerous masses, which in the lower half were thickly pressed together, while in the upper part of the organ they were arranged along the edge of the medullary portion. The cancerous affection involved also the sacro-lumbar lymphatic glands, the omentum, pancreas, liver, etc. In the kidney the beginning of the process could be seen in a noticeable hyperplasia of the epithelial cells, with an increase of the nuclei, and protoplasm and a progressive proliferation of the cells, so that finally the entire calibre of the renal tubules was filled by them, and the tunica propria, which could be distinctly recognized, was thrust forward at many points. The forms of the cells became more varied as their number increased. These changes were not uniform in all the tubules of the same region, and not even at all portions of the same tubule, so that sometimes portions were found intact, while adjacent to them were others in which the cancerous degeneration was fully advanced. No new growth of connective tissue could be found, so that the stroma of the cancer was furnished entirely by the tunica propria and the small amount of connective tissue beneath it. It was only in large masses of degenerated tissue in which no normal renal elements were to be found that there was any interstitial connective-tissue growth, and when here seen it had taken on a cicatricial appearance. Here, too, were seen spindle-formed cancer-cells in connective tissue, but no evidence of a transition from connective tissue into cancer-cells was found. Many of the tubules were not involved in the cancerous degeneration, but were simply atrophied. Both in the uninjured tubules and in those which had undergone degeneration were found hyaline cylinders, and in the right kidney many of the corpuscles of Malpighi had undergone amyloid degeneration, while in the left this was not found to be the case.

W. A.

FUNGUS ORIGIN OF ERYSIPELAS.—Dr. Wladimir Lukomsky publishes in *Virchow's Archiv*, 60ten Bd., 3tes u. 4tes Heft, the results of certain researches on the origin and nature of the poison of erysipelas.

After some preliminary remarks on various modern views of the affection, Dr. L. gives notes of two series

of cases, as well as of experiments made upon animals, etc.

His conclusions from the first series are as follows. "The following facts," he says, "are established:—1. The conclusions of other authors are confirmed, that severe and rapidly-spreading phlegmonous inflammation of the subcutaneous connective tissue, in which the cutis also takes a decided part, may be developed by the hypodermic injection of fluids containing organic germs.

2. The micrococci multiply rapidly in the connective tissue, and spread principally through the serous canals and lymphatic vessels.

3. This inflammatory process may be brought about by a fluid containing organic germs which at the same time shows no signs of putridity, as, for instance, fluids taken from living individuals. It follows from this that the existence of organic germs cannot in any way be regarded as a criterion of putridity.

4. Putrid (dead) fluids which do not contain micrococci and bacteria are not in themselves sufficient to bring about anything more than a local inflammation, which has no disposition to spread farther.

5. The contents of erysipelatous blebs free from organic germs cannot cause, where subcutaneously injected, any symptoms of disease.

From his second series of experiments Dr. Lukomsky draws the following conclusions:

1. Putrefying materials containing organic forms being placed in contact with a wound immediately bring about severe local inflammation, which may also comprehend the surrounding skin. This wandering disease-process cannot be distinguished in its general symptoms from the so-called erysipelas occurring in human beings.

2. The micrococci and bacteria penetrate the connective tissue by means of the serous canals, and wander by these paths still farther.

3. They are found especially in the peripheric portions of the localized inflammation, and more particularly just where the inflammatory process is making most rapid progress.

4. Erysipelas moves preferably in certain directions. When, for instance, the wound in these investigations on animals lies in the middle line of the back or in its immediate neighborhood, the process spreads with equal rapidity on one side and on the other towards the abdomen, more slowly behind, and still more slowly forward.

EPIDERMIC GRAFTS FROM THE SKIN OF THE RABBIT.—*L'Abeille Médicale*, No. 17, August, 1874, contains an article on this subject extracted from the *Rev. Méd. de l'Est*. After stating the fact that animal grafts are practicable, and giving various synonyms for the term "graft," the writer gives the following "precautions for conveniently performing transplantation:—"

1. If the borders of the ulcer are thick and the surface suppurates abundantly, they can scarcely be expected to heal. It is necessary, therefore, to alter the condition of the sore. For some days alcoholic washes should be used, and the dressing should contain glycerin. Transplantation should not be resorted to until the surface of implantation is covered with firm granulations and even a little dry.

2. Preparation of the grafts. A healthy rabbit should have a small portion of the skin of the back carefully shaved off at some point where the hair has been previously removed with sulpho-sulphuret of calcium. The fragment removed should contain a portion of the dermis and epidermis alone.

3. The fresh fragment should be transported to a portion of the sore previously designated, and which should be prepared by a few small incisions with a bistoury.

4. The fragment of epidermis should be fixed in its place by small strips of oiled paper, the ends of which extending beyond the edge of the sore are fixed by means of collodion. The wound should then be covered with a piece of linen soaked in glycerin and fenestrated; over this a compress of charpie, also soaked in glycerin or glycerole of starch, and a bandage over the whole. Collodion may be used to aid in fixing the bandage. The importance of using every means to prevent the graft from slipping is easily understood.

5. If the wound is in good condition, and but little suppuration is taking place, the dressing need not be removed for forty-eight hours. If, on the contrary, a certain amount of pus continues to be formed in spite of the precautions taken, the dressing should be changed at the end of twenty-four hours. If the fragment becomes fixed, it is slowly transformed, the pigment disappears, the animal epidermis is gradually dissolved, and there remains a mucous surface which easily cicatrizes.

The cicatrix thus obtained has remarkable vitality, and presents a much better appearance than cicatrices obtained by other means.

The writer concludes by remarking that there results from the facts stated the following:

1. Transplantation of epidermis from the rabbit to man can be performed with success.

2. In order that cicatrization shall take place, it is necessary that the graft shall be perfectly fixed. The operation then goes on from a centre of new tissue within the sore, which becomes a centre of cicatrization.

As soon as the extraneous integument once becomes firmly fixed, its pigment disappears, its epidermis disappears, and its cicatrix is from that time part and parcel of the human tissues. A. V. H.

CASE OF POISONING BY DIGITALIN.—Dr. Maguire writes a letter to the *Gaz. Hebdomadaire*, July 24, 1874, giving a case of accidental poisoning by this drug. The case was that of a woman suffering from some affection of the heart, for whom he had prescribed a granule of digitalin every evening.

The patient took it upon herself to swallow a *pinch* of granules,—an amount equal to one-fourth grain. In a few moments she was attacked by extreme præcordial anxiety, cold perspiration, nausea; finally, at three o'clock in the morning (six hours later) she vomited a small quantity of greenish, glairy matter, and experienced severe pain in the region of the stomach. Examined at eight o'clock the next morning, the præcordial anxiety had increased, and the vomiting was recommenced as soon as any liquid was taken into the stomach. The pulse was 90, and full, the action of the heart rhythmical and strongly accentuated, the face pale, the pupils normal, no headache, but cold perspiration, general malaise, bitter taste in the mouth; finally, the patient urinated very abundantly, without pain in the renal region; she preserved perfect consciousness. A cup of coffee containing a pinch of tannic acid was immediately administered. At eleven o'clock in the morning—that is, fourteen hours after the ingestion of the poison—the patient was seized with atrocious cramps in the thighs, calves, and feet; these pains returned every fifteen minutes; the pulse beat 104, full, regular, without intermissions. At 5 P.M. the pulse was 60, somewhat irregular: the face was injected, feebleness extreme, vomiting less frequent, pain diminished, tongue dry. The urine, which had been secreted very abundantly during the day, became entirely suppressed the following night. A little milk and soup were given, and were retained by the stomach. During the next day the patient's condition gradually improved; by night the pulse beat 72, rarely intermittent. In the

course of the following day all symptoms improved, the bitter taste in the mouth and the extreme feebleness alone being persistent for some time. A. V. H.

WOUNDS OF THE HEART.—F. Steudener (*Berliner Klin. Wochenschrift*, 1874, No. 7) had the opportunity of making a post-mortem examination of the body of a suicide who shot himself just beneath the left nipple. The ball, which was small, entered the muscular tissue of the heart, but did not pass entirely through it. Death followed from exhaustion fifteen weeks after the attempt at suicide was made. After inflicting the wound, the patient fell to the ground, but retained consciousness. Soon afterwards, it was noticed that there was both sensory and motor paralysis of the lower extremities. Physical examination of the heart showed that the area of dulness was normal, and also revealed the existence of an indistinct murmur, which upon the following day was found to be a friction-sound indicative of pericarditis. Pneumothorax of the left side was also present, which had forced the heart over towards the right side; the pulse was rapid and small; and below the navel there was complete loss of sensibility, with paralysis of the bladder and rectum. During the three following days the symptoms became more marked, and then as the wound began to heal they became less marked, but the paralysis continued, and a bed-sore which rapidly spread made its appearance. Upon examination of the body after death, the diminution in size of the muscles which had not been paralyzed, as compared with the increase of those paralyzed through fatty degeneration, was quite marked. The lungs were found to contain air, and there were cicatricial pleuritic adhesions and contractions of the upper lobes. The heart was somewhat hypertrophied, and at all points attached to the pericardium by fine fibres of connective tissue. On the left ventricle was found a furrow two centimetres in breadth, filled with connective tissue which started at the apex of the heart, and beneath this cicatricial tissue the muscle of the heart was but 1.5 mm. in thickness. The beginning and end of this track of connective tissue corresponded to perforations in the pericardium, in the neighborhood of which were found grains of powder. The spinal column was entirely severed between the tenth and eleventh thoracic vertebræ, and the ball was found in the right side of a vertebra. Both portions of the vertebral column were joined by bands of connective tissue; the lower segment was softer than the upper, and the gray substance could be but indistinctly seen. W. A.

THE TREATMENT OF VENEREAL BUBOES.—Sauszinski (*Centralblatt für Chirurgie*, No. 6, 1874) has adopted the method of opening buboes by a small perforation, as was advised by Ricord and later by Zeissl, and has tried it in eighty-two cases of this complication of venereal disease. The bubo is opened with a narrow bistoury, the pus is pressed out through the wound, and it is then dressed with a graduated compress moistened with lead-water, over which a small sack filled with sand is laid. The whole dressing is then fastened by means of a Spica bandage, and the patient is confined to his bed for the first few days. At first the compress is renewed twice during the day, but later, when suppuration has diminished, only once, the wound being washed with warm water at each dressing. The sack of sand is used until the edges of the wound become attached to the tissues beneath, when the dressing is changed to charpie and adhesive strips. The advantages claimed for this method of treatment over that by free incision are that the risks of having distinctive ulcerative processes in the wound are much less, and the time needed for its closure is shortened from forty-nine to twenty-eight days. W. A.

PHILADELPHIA MEDICAL TIMES.

A WEEKLY JOURNAL OF

MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY

J. B. LIPPINCOTT & CO.,

715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, SEPTEMBER 19, 1874.

EDITORIAL.

PROF. JEFFRIES WYMAN.

THE news of the death of Prof. Jeffries Wyman will be received with great sorrow. He represented a type of intellect so rare, produced such excellent results, influenced for good so much that is best among the works of the younger anatomists, and withal bore his great faculties so meekly, that he was justly esteemed as one of the foremost of men.

Everything that he did wore the impress of a strong individuality. None of his memoirs are of great length, but they embraced an unusual variety of subjects. His style was clear, and therefore attractive, and his matter as remarkable for what it suggested as for what it directly taught. He anticipated in his paper on "Spontaneous Generation" the brilliant labors of Bastian; he was the first to invite attention to the plan of arrangement of the cancelli of bone, antedating Wolfermann by many years; he exploded the notion of the mathematical value of the cells of the honey-comb; he derived results of exact value from the difficult field of intermembral homologies and antero-posterior symmetry. He also contributed a valuable memoir on the asymmetry of the human cranium, was the first to draw attention to the curious flattening of the tibia of North American Indians, and also gave the original description of the skeleton of the gorilla. He added to our knowledge of embryology and the anatomy of the nervous system in two of his most elaborate papers.

As an example of the accuracy of his information, we may mention the service he rendered in the famous Webster-Parkman case. It will be remembered that portions of the body of the murdered man had been mutilated and burned. The débris containing the suspected remains were given to Prof. Wyman for examination, who, in his report, accurately placed and described twelve minute fragments of the skull, with some portion of the trunk and the extremities. It is said that at one time a favorite amusement of his was to exercise his skill in identification by restoring in position the fragments of a bone he had previously comminuted.

Prof. Wyman's powers of work had been seriously impaired by the encroachments of consumption,—the disease of which he died. He had been compelled for several years to live in Florida during the winters, but not to rest, for his pen during these enforced visits was active in describing the shell-heaps of that section of the country. From the examination of some of these he deduced—chiefly by the condition in which human bones were found—that cannibalism must have been a long-standing custom among the aborigines frequenting the mounds.

In more than one respect Prof. Wyman resembled John Goodsir. He had the same splendid power of patient observation conjoined to the rare faculty of happy and profound speculation. He resembled him also in temperament, and—may we add?—in the somewhat desultory character of his work and carelessness of his own claims. We hope that Prof. Wilder—Wyman's best-known pupil—will do for his preceptor what has been done for Goodsir,—collect and edit the memoirs of this great and good man.

PHILADELPHIA HOSPITAL.

AS most of our readers know, we have time and again denounced this institution as entirely behind the requirements of the age. We have also stated that the Board of Guardians, in our opinion, did what they could with the amount of money at their disposal; that the fault of the managing board was not in maladministration of their trust, but in that they did not lay open the hidden places of the institution under their charge, and appeal to Councils and citizens for sufficient money to place the hospital upon a proper footing.

Within the last two years the composition of the governing board has been materially altered, and we are glad to be able to bestow a meed of praise upon it and upon the steward which it has chosen.

It is true that little has yet been actually accomplished; but there are indications of a better spirit and of a determination to improve the condition of affairs. The pride of the old board appeared to be to demonstrate how cheaply they could run the hospital; the new board seem to recognize the fact that there is something of more value than money. The present steward, Major Phipps, appears to be alive to the needs of the place, and to be anxious to do what is right in the matter. In his annual report just received he points out things which ought to be altered and improved, although the expense would be heavy,—confessing tacitly the great and pressing need there is of change. The Receiving Ward has long been a horrible place, and we learn that the board is to meet the Council Committee of Finance to obtain an appropriation with which to build a new one. We are both glad and sorry for this: glad, because it indicates a right spirit in the ruling board, and because the need of a *temporary* structure as a present relief is so great; sorry, lest so large an amount of money should be spent as to add new strength to the accursed union of the living and the dead, of the unfortunate sick and the pauper.

Will patching make the garment of a century ago a thing of beauty or of service? The whole plan upon which the almshouse exists is cruelly wrong, unjust, and unjustifiable, even by the merest motives of policy. Even the ambulance system recently inaugurated is, from its association, a curse rather than a blessing. A stranger is hurt in the streets of the city; the telegraph summons aid; he is borne by the ambulance to—where? To a ward filled with paupers, to a bed prepared by paupers, to the improper association, nursing, and food, with all the other inconveniences necessarily connected with an institution whose attendants are chiefly chosen from the ranks of paupers. Think of a city like Philadelphia herding the honest poor in their hour of sickness with the pauper and the outcast! A city of nearly a million of inhabitants with no municipal hospital, save as a department of its almshouse! No, gentlemen of the Board of Guardians, however honestly you strive, whatever minor reforms you institute, your work will be as naught, and the responsibility of human demoralization, if not of human life, will be upon you, unless you boldly place the truth before the community, and tell this city, which can spend millions upon its pleasure-bridges, that its charity fails in the fountain-head, and that its municipal hospital, which ought to be the chiefest of its jewels, is to-day a by-word of reproach, a fountain of demoralization and disgrace.

CORRESPONDENCE.

TRANSACTIONS OF THE NEW YORK SOCIETIES.

AT the meeting of the New York Neurological Society, held September 7, Clinton Wagner, M.D., read a paper on "Certain Nervous Diseases of the Throat."

After mentioning several cases occurring in his own practice, he enumerated as the causes of functional loss or impairment of the voice—hysteria; violent mental action from fright, joy, or grief; general debility; catarrh; overstraining of the voice in singing, loud talking, or prolonged exertion; reflex action; mechanical causes; poison: each of which was carefully reviewed.

In the way of treatment, he said that in simple, uncomplicated functional aphonia or dysphonia, local remedies which bring about a reflex contraction of the muscles of the larynx concerned in voice-production will be found in many cases all that is necessary. Particularly is this the case in aphonia of hysteria. Electricity applied directly to the vocal cords in this variety rarely fails to restore the voice.

Lotions of nitrate of silver, perchloride of iron, cupri sulph., zinci sulph., varying in strength from half a drachm to two drachms to the ounce, applied with a brush or inhalations of the same through the steam atomizer, or in the form of spray produced by compressed air, through Sass's tubes, are very useful in cases in which there is congestion of the mucous membrane of the cords and adjacent parts. Vapor inhalations of the *ol. fol. pini sylvestris*, creasote, or *ol. junip. anglici*, are serviceable in cases of dysphonia from a relaxed condition of the vocal cords.

Where the aphonia depends upon or exists in connection with an inflamed condition of the mucous membrane of the larynx, the remedies enumerated above should be employed; but if that condition does not exist, the sheet-anchor in the treatment is electricity, and time is lost by resorting to other means of treatment. This agent is not a new one in treating aphonia. In 1800, Grafengiesen, of Berlin, applied it to the neck; but Mackenzie has the credit of having first applied it to the mucous membrane of the larynx over the paralyzed muscle. In using it, a band is fastened around the neck, to which one pole is attached over the thyroid cartilage; the other pole is fastened to a metallic sound, bent at the proper curve, and passed over the epiglottis into the larynx by the aid of the laryngoscope. It is immaterial whether the negative or the positive pole is introduced into the larynx.

The constant current is generally employed, from a twenty-cell battery. Never more than from four to eight cells are used for internal applications. In cases of long standing the interrupted current is sometimes employed by the essayist, and in such cases more decided results have been obtained than from the constant current, probably owing to the greater muscular excitation produced. As regards pain, the patients complain that the constant current is more severe.

Other means of treatment have been tried with success. Burns has cured cases by introducing a mirror, and causing the patient to utter vowel-sounds, and then combining them with consonants.

In regard to the early treatment of impairment of the voice occurring in singers and public speakers, the physician should insist above all things upon absolute rest of voice for weeks or even months; at the same time employing locally the mild astringents to relieve the congestion, after which the constant current.

In laryngeal neuralgia, which is occasionally met with as a true neurosis and independent of any other morbid process in the same individual, the treatment which Dr. Wagner has found most useful has been large doses of the tincture of iron and quinine, and insufflation of tannic acid and morphia into the larynx. Aconite liniment over the seat of pain gives temporary relief. Hypodermic injections of morphia are useful. Electricity in the form of the faradic current has had the effect of increasing the pain, from the muscular excitation it produces; and the constant current has failed to give the relief claimed for it by others who have used it. In nervous sore throat, an affection difficult to diagnosticate and still more so to treat satisfactorily, local applications of iron in the form of spray, and morphia applied with a brush, gave great relief. It sometimes accompanies hysteria, in which case the general health must be improved by tonics, generous diet, and change of air. If the patient has lived in the damp sea-air of the coast, a change to a dry, mountainous region will be found beneficial, and *vice versa*. Local applications should be of a mild, soothing character. Much benefit in the hands of the essayist has been derived from morph. sulph., gr. vi to $\frac{3}{4}$ i aqueæ, applied by means of the brush to the parts complained of; also, sprays of the same, or weak solutions of zinc or iron. W.

NEW YORK, Sept. 8, 1874.

MEETING OF THE BRITISH MEDICAL ASSOCIATION.

NORWICH, ENGLAND.

TO THE EDITOR OF THE PHILADELPHIA MEDICAL TIMES:

DEAR SIR,—On the third day of the meeting of the Association, Mr. Lund, of the Royal Infirmary of Manchester, read before the Surgical Section an interesting paper on "Incision *versus* Excision of the Knee-Joint in Children." He presented his plan of dividing subcutaneously, and under antiseptic influence, the inter-articular ligaments of the joint, with peculiar hook-like knives, and following the operation by extension of the limb, in certain cases ordinarily submitted to excision.

Mr. Lund also showed in the Museum of the Association a number of ingenious appliances for the treatment of joint-disease and for other surgical uses.

In the Section on Public Medicine, its President, W. H. Michael, Esq., barrister-at-law, said that "public medicine, which might be taken to include any medical

service paid for out of funds raised by taxation or rates, must of necessity have to deal with other phases of medical practice than those within the sphere of the private medical practitioner, so called.

"There was a misconception on the part of some friends of sanitary effort tending in a direction more dangerous to progress than absolute opposition. It was asserted as probable that by preventive medicine we might indeed save life, but that we saved only the lowest, least valuable, and most imbecile form of it, and this tended to the degeneration, while we added to the number of the population. Nothing could be more fallacious, or, if unanswered, would completely while insidiously check and paralyze sanitary action. It was attributed to the late illustrious Professor Liebig that he enunciated the axiom that disease began where resistance ended; and if so, this sentence contained the germ of the error into which writers like Kingsley and Herbert Spencer had fallen when writing on the subject of public health. The real fact was that sanitary measures would tend to perpetuate a race endowed with greater power and vitality than that of any preceding age. Besides this, it must be borne in mind that it was not the weak, the decrepit, and the infirm who were always the victims of zymotic or preventible diseases, seeing that there were whole classes of those diseases which especially selected for their victims those who were in the prime of life,—the strong, the active, and the robust."

On the same subject, at the general meeting, Dr. Rumsey presented a draft of a report of the State Medical Qualification Committee, which recommends the establishment in each division of the kingdom of a uniform qualification in state medicine, to be held in future, besides the license to practise, by all persons before they are elected to hold any public medical office the salary of which is paid out of rates or taxes.

Dr. Sims delivered an address on the subject of the management of the pedicle in ovariectomy, recanting some of the objections he formerly made to the use of the clamp, and stating his present practice of using a very simple and readily extemporized clamp of thick iron wire, adjusted on the pedicle under tension of an écraseur.

Mr. Cadge, of the Norwich Hospital, delivered an excellent address before the Surgical Section on the subject of urinary calculus, particularly in reference to the extraordinary prevalence of the affection in that particular part of the country, and which is greater than in any other region in the world. I was particularly impressed with his reference to such factors in the tendency to calculus as the use of water impregnated with lime, in combination with the habits of the people in consuming food of a character likely to produce indigestion. He spoke of the common diet of boiled dough in the form of greasy dumplings or puddings, with sour beer as a beverage. I thought of somewhat similar influences that exist in some limestone regions of America where calculus is very prevalent, such as the diet of heavy, sodden, and doughy bread, and the greasy

and indigestible products of the inevitable frying-pan, which are notoriously productive of indigestion of an acid form. Mr. Cadge has *never seen calculus among children who were fed on a proper milk-diet*, and he accounted for the comparative exemption of Irish and Scotch children by their universal consumption of such food.

During the continuance of the meeting, some French physicians attempted to give demonstrations of the antagonism of alcohol and absinthe, by injecting those substances alternately into the veins of animals. The demonstration, although not carried out to the extent contemplated, was quite clear; but the necessary vivisections led to much excitement and violent opposition, that brought the affair to a sudden conclusion. The incisions made to expose the femoral vein and to prepare it for the injection were made without anæsthesia, and were done in an unsurgical and bungling manner. It may have been essential for proper success of the experiments to avoid the impression of anæsthesia on the nervous system of the animals, but it does seem practicable that the operations of exposing the vessels might have been previously performed under anæsthetics, thus allowing full time for recovery from their influence before the physiological experiments were made. The opposition to the vivisections, which were performed in a small room adjoining that of the general meeting, became violent and turbulent, especially under the influence of some excited citizens of the place who had made their way into the room.

One dog had been sacrificed to the toxic injection, and another was recovering under the antidotal influence of an antagonistic remedy, when the proceedings were suddenly concluded, and some previously-condemned cats were literally "let out of the bag." The sentiment was freely expressed that vivisection without anæsthesia for scientific *investigation* may be proper, but for the mere *demonstration of known facts* will not be tolerated by the profession. Such views may not be in accordance with "the way they do things in France," but the general impression of those present evinced the conviction that science and humanity should work in harmony.

Mr. Croft, of St. Thomas's Hospital, London, presented the subject of "Sub-periosteal Excision of the Hip-Joint," after the general manner of Dr. Sayre, of New York, and which that surgeon had introduced into European practice.

Dr. J. Marion Sims, of New York, spoke of his experience of the subject from his observation of operations performed by Dr. Sayre, and of the excellent results obtained.

Dr. Sims made the following remarks on Nélaton's method of resuscitation from chloroform-narcosis:

"Dr. Charles James Campbell, the distinguished accoucheur of Paris, has recently written two papers on anæsthesia in obstetrics,* in which he ably sustains the views long taught by Nélaton, that death from chloro-

form is due to syncope or cerebral anæmia. And, among other strong arguments to prove his position, he gave a graphic description of a case of chloroform-narcosis which occurred in my practice in Paris, where M. Nélaton, by his method, unquestionably saved the life of the patient. She was young, beautiful, and accomplished, and belonged to one of the oldest and best families in France. Married at twenty, she gave birth to her first child a year afterwards. The head was enormous (hydrocephalic), impacted in the pelvis nearly twenty-four hours, and the delivery of a dead child was ultimately accomplished with instruments. Dr. Bouchacour, of Lyons, was called in consultation, and applied the forceps. In a week afterwards, the urine began to dribble away, and in a fortnight an immense slough was thrown off. The case, surgically considered, was one of the most interesting I ever saw, and the operation was one of the most difficult I ever performed on any one in her station in life. The base of the bladder was destroyed, and the fundus fell through the fistulous opening: it was therefore inverted and protruded between the labia majora as a herniary mass of the size of an apricot, its external covering being the internal or lining membrane of the bladder, which was of a deep vermilion-red color. The vaginal portion of the cervix uteri and the posterior cul-de-sac were destroyed; and by the reparative process the cervix and the posterior wall of the vagina were blended into one common cicatricial mass, which was firm, inelastic, and immovable. The case appeared desperate, and M. Nélaton had pronounced it incurable. A preparatory operation was necessary,—viz., to open the cervix uteri by dissecting it from the posterior wall of the vagina, and thus to reconstitute the canal of the vagina up to the canal of the cervix, and by a subsequent operation to draw forward the flap thus formed, secure it to the neck of the bladder anteriorly, and thereby close the fistula. The first or preparatory operation was performed at the country-house of the family, near Dijon, on November 3, 1861, Dr. Dugast, of Dijon, assisting, and giving chloroform. The second, or operation for the radical cure, was performed on the 19th of the month, at St.-Germain, about an hour's distance from Paris by rail. M. Nélaton, Dr. Campbell, Dr. Beylard, Dr. Johnston, and Mr. (now Dr.) Alan Herbert, were present. I seldom give an anæsthetic in private practice for operation on the walls of the vagina, as the pain is generally not sufficient to call for it. But in this case, as the slightest touch was unbearable, an anæsthetic was indispensable. Dr. Campbell was selected by the family, as well as by M. Nélaton and myself, to administer the chloroform, especially as he was in the daily habit of giving it in his large obstetrical practice, and we all had entire confidence in his caution, skill, and judgment. The patient was soon anæsthetized. The operation was begun at 10 A.M., and I thought it would require about an hour to finish it.

"Many years ago I imbibed the convictions of my countrymen against chloroform in general surgery, and have always used ether in preference, never feeling the

* 1. Mémoire sur l'Anesthésie obstétricale; 2. Etude sur la Tolérance anesthésique obstétricale, par le Dr. Charles James Campbell, ancien Interne de la Maternité de Paris, ancien Chef de Clinique obstétricale de la Faculté de Paris. G. Masson. 1874.

least dread of danger from it under any circumstances. It is otherwise with chloroform; and in this particular case I felt the greatest anxiety, frequently stopping during the operation to ask Dr. Campbell if all was going on well with the patient. At the end of forty minutes the sutures (twelve or thirteen) were all placed, and ready to be secured, and I was secretly congratulating myself that the operation would be finished in a few minutes more, when all at once I discovered an unusual bluish livid appearance of the vagina, as if the blood were stagnant, and I called Dr. Johnston's attention to it. As this lividity seemed to increase, I felt rather uneasy about it, and I asked Dr. Campbell if all was right with the pulse. He replied, 'All right; go on.' Scarcely were these words uttered, when he suddenly cried out, 'Stop! stop! No pulse, no breathing;' and, looking to M. Nélaton, he said, 'Tête en bas, n'est-ce pas?' Nélaton replied, 'Certainly; there is nothing else to do.' Immediately the body was inverted, the head hanging down, while the heels were raised high in the air by Dr. Johnston, the legs resting one on each of his shoulders. Dr. Campbell supported the thorax. Mr. Herbert was sent to an adjoining room for a spoon, with the handle of which the jaws were held open, and I handed M. Nélaton a tenaculum, which he hooked into the tongue and gave in charge to Mr. Herbert; while to Dr. Beylard was assigned the duty of making efforts at artificial respiration, by pressure alternately on the thorax and abdomen. M. Nélaton ordered and overlooked every movement, while I stood aloof and watched the proceedings with, of course, the most intense anxiety. They held the patient in this inverted position for a long time, before there was any manifestation of returning life. Dr. Campbell in his report says it was fifteen minutes, and that it seemed an age. My notes of the case, written a few hours afterwards, make it twenty minutes. Be this as it may, the time was so long that I thought it useless to make any further efforts, and I said, 'Gentlemen, she is certainly dead, and you might as well let her alone.' But the great and good Nélaton never lost hope, and by his quiet, cool, brave manner he seemed to infuse his spirit into his aids. At last there was a feeble inspiration, and after a long time another, and by-and-by another; and then the breathing became pretty regular, and Dr. Campbell said, 'The pulse returns, thank God; she will soon be all right again.' Dr. Beylard, who always sees the cheerful side of everything in life, was disposed to laugh at the fear I manifested for the safety of our patient. I must confess that never before or since have I felt such a grave responsibility. When the pulse and respiration were well re-established, M. Nélaton ordered the patient to be laid on the table. This was done gently. But what was our horror when at the moment the body was placed horizontally the pulse and breathing instantly ceased! Quick as thought the body was again inverted, the head downwards and the feet over Dr. Johnston's shoulders, and the same manœuvres as before were put in execution. Dr. Campbell thinks it did not take

such a long time to re-establish the action of the lungs and heart as in the first instance. It may have lacked a few seconds of the time; but it seemed to me to be quite as long; for the same tedious, painful, protracted, and anxious efforts were made as before, and she seemed, if possible, more dead than before; but, thanks to the brave men who had her in charge, feeble signs of returning life eventually made their appearance. Respiration was at first irregular and at long intervals; soon it became more regular, and the pulse could then be counted; but it was very feeble and would intermit. I began again to be hopeful, and even dared to think that at last there was an end of this dreadful suspense, when they laid her horizontally on the table again, saying, 'She is all right this time.' To witness two such painful scenes of danger to a young and valuable life, and to experience such agony of anxiety, produced a tension of heart and mind and soul that cannot be imagined. What, then, must have been our dismay, our feeling of despair, when, incredible as it may seem, the moment the body was laid in the horizontal position again, the respiration ceased a third time, the pulse was gone, and she looked the perfect picture of death! Then I gave up all as lost; for I thought that the blood was so poisoned, so charged with chloroform, that it was no longer able to sustain life. But Nélaton, and Campbell, and Johnston, and Beylard, and Herbert, by a consentaneous effort, quickly inverted the body a third time, thus throwing all the blood possible to the brain, and again they began their efforts at artificial respiration. It seemed to me that she would never breathe again; but at last there was a spasmodic gasp, and after a long while there was another effort at inspiration, and after another long interval there was a third; they were 'far between;' then we watched, and waited, and wondered if there would ever be a fourth. At length it came, and more profoundly, and there was a long yawn, and the respiration became tolerably regular. Soon Dr. Beylard says, 'I feel the pulse again, but it is very weak.' Nélaton, after some moments, ejaculates, 'The color of the tongue and lips is more natural.' Campbell says, 'The vomiting is favorable; see, she moves her hands; she is pushing against me.' But I was by no means sure that these movements were not merely signs of the last death-struggle, and so I expressed myself. Presently Dr. Johnston said, 'See here, doctor; see how she kicks; she is coming round again;' and very soon they all said, 'She is safe at last.' I replied, 'For heaven's sake, keep her safe; I beg you will not put her on the table again till she is conscious.' This was the first and only suggestion I made during all these anxious moments, and it was acted upon; for she was held in the vertical position till she, in a manner, recovered semi-consciousness, opened her eyes, looked wildly around, and asked what was the matter. She was then, and not till then, laid on the table, and all present felt quite as solemn and as thankful as I did; and we all in turn grasped Nélaton's hand and thanked him for having saved the life of this lovely woman.

"In a few minutes more the operation was finished, but, of course, without chloroform. The sutures were quickly assorted and separately twisted, and the patient put to bed; and on the eighth day thereafter I had the happiness to remove the sutures in the presence of M. Nélaton, and to show him the success of the operation.

"I have detailed the circumstances of this interesting case at great length, because I believe it goes as far to establish a principle of treatment as any one case ever did, or possibly can."

"If the recovery had been complete and perfect with the first effort at reversing the body, there might have been a doubt whether the vertical position was really the cause of resuscitation; but when the horizontal position was again and again followed by a cessation of all evidence of life, and when life was again and again re-established by a position that favored only the gravitation of the blood (poisoned as it was) to the brain, the inference is very clear that death in such cases is due to syncope or cerebral anæmia. Exhaust the brain of blood in any way, and death follows. Fill it speedily with blood again, and life returns.

"I have another case to relate, which goes far to establish the principle of treatment in chloroform-narcosis so forcibly illustrated by the case at St.-Germain.

"In January, 1873, I amputated the cervix uteri at the Woman's Hospital, drew the vaginal tissue over the stump, and secured it by silver sutures. The junior house-surgeon gave the anæsthetic. When the operation was nearly finished, he cried out, 'The patient has stopped breathing,' and immediately added, 'She has no pulse.' As before stated, I always use ether as an anæsthetic, and could not realize the fact that my patient was in any danger whatever till I was told that they were giving her a mixture of chloroform and ether (one part to four) which some of the surgeons had been using a few days previously. On examining the patient, I found her, as it were, dead; there was not the slightest muscular rigidity; the arms and head fell by their own gravity in any way they were directed; the neck was as limber as if it were a mere band of soft linen stretching from the head to the trunk; there was not the least sign of breathing or of the pulse; she was, to all intents and purposes, dead; and I believe she would certainly have remained so if she had been left alone; and I doubt very much whether she could possibly have been resuscitated by any other method than that of Nélaton's.

"I quickly inverted the body, and had it held thus, and then I shook the thorax, agitating the head laterally, so as to add an impetus to the movement of the blood, which, with the body in this vertical position, would naturally gravitate towards the brain; the jaws were held asunder, and the tongue hooked with a tenaculum and pulled forward. In a few minutes the breathing was re-established, and then the pulse returned; and soon the patient was placed again on the table in the lateral semi-prone position in which all my operations on the uterus are performed; and the operation was finished, but without any more of the anæsthetic.

"These two cases comprise my personal experience with Nélaton's method in chloroform-narcosis.

"The *New Orleans Medical and Surgical Journal* for November, 1873, says, 'In the course of an extended experience in the administration of chloroform, it has happened three times to Dr. M. Schuppert that, to all appearances, the narcotized subject died,—that is, respiration ceased, the heart stopped beating, and muscular contractility became extinct. The method he adopted for resuscitating these patients consisted in reversing the body, either by hanging them up by the feet, or laying them over a bed or table, so that the greater part of the body with the head hung down. In that position artificial respiration was also tried. In one case five minutes elapsed before there was a natural inhalation. All of them recovered. Dr. Schuppert believes that in cases of death from chloroform the primary cause of the cessation of the respiration and circulation rests in anæmia of the brain, and not in impregnation of the blood with carbonic acid.'

"Another American authority, Dr. E. L. Holmes (*Chicago Medical Journal*, September, 1868), says that whenever there is any failure of the heart's action, as is nearly always the case, the body should be laid at an angle of 40°, with the head downwards, so as to favor the passage of arterialized blood to the brain.

"I take it for granted that Dr. Schuppert and Dr. Holmes must have obtained their knowledge of this method of resuscitation either directly or indirectly from the teachings of Nélaton; for he had for years been in the habit of explaining his method in his lectures and at his *cliniques*, and Dr. Johnston published an account of it in the American papers in 1861. Ten years ago there was a story prevalent in Paris that M. Nélaton had derived the hint of reversing the body in chloroform-poisoning from a discovery accidentally made by his little son, then some seven or eight years old; that the little boy had killed some mice with chloroform; that, without thought or reason, he had taken up a dead mouse by the tail, and was twirling it round, when, to his surprise, it began to manifest signs of life, and recovered entirely, while the mice left lying were dead; and that the great surgeon was thus taught a great lesson, if not by babes and sucklings, at least by a little boy. This is a very pretty story as it is, and it seems a pity to spoil it. A few days ago, when in Paris, I called to see young Nélaton (who is now a student of medicine, and will graduate next year), and I asked him for the facts of the mouse-story. He said that when they lived on the Quai Voltaire the house was infested with mice; that great numbers were caught in traps almost daily; that he was in the habit of killing them with chloroform by covering the trap with a napkin and pouring the chloroform on it; and that his only idea was that of an easy death for the mice. One day, when he had given a happy dispatch to some mice, his father accidentally came into the room, and, seeing the dead mice, he told his son if he would take up one by the tail and hold it with the head downwards, it would revive, while the others would not. He did this, and found it was

true. And he told me that he had, when a boy, performed the same experiment on mice some forty or fifty times or more, and always with the same unvarying result. He says that he has often heard his father speak not only of the case that occurred at St.-Germain, but of other cases that he had saved in the same way before the time of the mouse-story, which dates back to 1857 or 1858.

"As the facts now laid before you fully explain themselves, it is unnecessary for me to indulge in any lengthened remarks on the subject. In my own country the accoucheurs often use chloroform, and the surgeons mostly use ether. I believe there has not as yet been a single death from chloroform given during labor; while deaths from it in general surgery occur constantly and for unimportant operations. There must be a reason for this. I believe that it can be explained only on the theory that death from chloroform is, as a rule, due to syncope or cerebral anæmia. 'Now, we know that in active labor there can be no cerebral anæmia, for every pain throws the blood violently to the head, producing fulness and congestion of the blood-vessels, thereby counteracting the tendency of the chloroform to produce a contrary condition. It may be said that the recumbent position has some influence in determining the safety of chloroform in labor; and so it has; but it gives no immunity under other circumstances. Chloroform given intermittingly, as in labor, is thought to be less dangerous; but patients in labor are often kept for hours under its influence with safety, and occasionally it is necessary to produce complete and profound narcosis in some obstetrical operations; and yet I believe I can safely reiterate what I have already said, that no woman has as yet died in labor from the effects of this anæsthetic. In puerperal convulsions, where the brain is believed to be overcharged with blood,—and that, too, when the blood is known to be poisoned with urea,—we formerly bled the patient, and we do so now sometimes; but our chief remedy is chloroform, which acts by arresting spasmodic movements, and by producing that very state of cerebral anæmia so necessary to a successful result. Whether puerperal convulsions are less frequent in labors under chloroform than in those without it, I do not know.

"I believe that obstetrics may take a lesson from Nélaton's method of resuscitation, by adopting it in cases of threatened death from post-partum hemorrhage. Let us not be satisfied with simply placing the head low; but let us, in addition to the means usually adopted, invert the body, and throw what little blood there is left in it wholly to the brain. I have never seen a death from uterine hemorrhage; but, from recollections of the few alarming cases I have witnessed, I now feel sure that recovery might have been hastened if I had known of and adopted Nélaton's method of inversion.

"Whether death from chloroform is due to cerebral anæmia or not, it is at least safe to adopt Nélaton's method in all cases of supposed or threatened danger; but I think the safest plan is to relinquish the use of

chloroform altogether, except in obstetrics. The frequent cases of death from the use of chloroform in surgical operations that have occurred among us, even of late, should warn us to give up this dangerous agent, if we can find another that is as efficient and at the same time free from danger. Ether fulfils the indications to a remarkable degree; but, while it is safe, it is, unfortunately, unpleasant to the physician and bystanders, as well as to the patient. He who will give us an anæsthetic as pleasant to take as chloroform and as safe as ether will confer the greatest boon upon science and humanity."

R. J. LEVIS, M.D.

GLEANINGS FROM OUR EXCHANGES.

DIFFERENTIATION OF INTESTINAL INVAGINATION.—Dr. O. Leichtenstein, in an article on invagination (*Archiv f. Prakt. Heilk.*, 4, 1873), refers to the following points for the differentiation of invagination of the small from that of the large intestine: 1. Invagination of the small intestine but rarely occurs during the first year of life, as also rarely during childhood in general. 2. In adults, the course of the attack in invagination of the ileum is more rapid, the phenomena more severe, than in ileo-cæcal and colon invaginations. Chronic cases are rare in invaginations of the small intestine, more frequent in those of the ileo-cæcum and colon. Severe symptoms of collapse occur more frequently in the beginning of the disease. 3. Muco-sanguinolent discharges are the rule in all invaginations, whatever their seat. Fecal evacuations, entirely normal in character (after preceding diarrhoea), were observed in ileo-cæcal invaginations, once in a colon invagination, the patient being an adult. 4. Meteorism is a very variable symptom. It is usually absent in ileo-cæcal invaginations. In invaginations of the descending colon it was frequently recognized as affecting the transverse colon, and subsequently spread over the whole abdomen. In invagination of the ileum it was occasionally found to be confined principally to the central abdominal region, with exemption of the lateral portions and epigastrium. 5. Tenesmus is rare in invagination of the ileum, frequent in that of the colon and ileo-cæcum. 6. The tumor is usually absent in ileum invagination. Its seat in the centre of the hypogastrium speaks for this variety; when situated in the cæcal region, especially when it remains stationary for some time, it indicates ileum or ileo-cæcal invagination. The spread of the tumor, when occurring suddenly and corresponding to the course of the colon, speaks more for ileo-cæcal, less for colon invagination, and excludes ileum invagination. The seat of the tumor in the left lateral portions of the abdomen would indicate ileo-cæcal or colon invagination. The tumor can never be felt in the rectum, and prolapse through the latter never occurs in uncomplicated ileum invagination. Changes in the consistency, occurrence, and disappearance of the tumor were especially observed in ileo-cæcal invagination.—*New York Medical Journal*, Sept. 1874.

LUXATION OF THE TENDON OF THE TENSOR VAGINÆ FEMORIS.—Dr. Ardenet, of Foissac, reports the following case: He was recently consulted by a laborer, who stated that, while engaged in the field at labor which required great efforts on the part of the inferior extremities, he suddenly experienced an acute pain in the right knee. On examination, the most apparent symptom was the acuteness of the pain when the right leg was moved. The leg was flexed, and with some

difficulty the author succeeded in extending it. A small tumor was then found located behind and above the external condyle of the femur, which was very tender on pressure, and connected with a cord which extended downward and from within outward. The author thereupon made the diagnosis of luxation of the tensor of the fascia lata, produced by extraordinary muscular effort, and after several attempts succeeded in replacing it in its normal position. This was accomplished by exerting pressure from without inward with the thumb of the right hand while the left sustained the limb. As soon as the tendon recovered its normal position, anterior to the external condyle, the patient experienced complete relief and could walk without pain or difficulty, and on the following day returned to his customary duties.—*New York Medical Journal*, Sept. 1874; from *Journal de Thérap.*, 1874.

A HERMAPHRODITE.—The *London Lancet*, Aug. 22, 1874, gives the following account of an individual who appears to be a true hermaphrodite:

The breasts present all the characters of the female sex, so that the upper part of the trunk has quite a feminine appearance. The generative organs, on the other hand, constitute an apparatus composed of parts belonging to both sexes. It appears as if the right side belongs specially to the male (and it is to be noted that the right side of the face looks masculine as compared with the left). In the centre a rudimentary penis is observed, the glans of which is somewhat furrowed at its end. The urethra opens at the base of the penis, forming a scrotal slit, this disposition giving rise to a variety of hypospadias. The prepuce is largely developed, very loose, and bound with a thick indented ridge, as is seen in the nymphæ. On the right side is seen the scrotum containing one testicle, whilst none exists on the left. The whole scrotum looks much like the labia majora, and when the finger is introduced between the two pendent halves and under the penis, it finds a cavity much resembling the vagina, though ending in a cul-de-sac. A female catheter, introduced into the meatus, and pushed horizontally (when the individual is standing), comes probably against a rudimentary uterus. When the catheter is directed upwards, it passes into the bladder.

This individual regularly menstruated through the meatus urinarius up to the age of forty-four, so that it must be inferred that the ovaries are more than rudimentary. Doubts as to the reality of menstruation in this case were raised; but the testimony of Recklinghausen, Kölliker, and Scanzoni, who saw the function performed, is sufficient to settle the question. Hence we find, in the same being, the combination of the secreting organs belonging to both sexes. Spermatozoa have been found in the liquor seminis. The propensities of both sexes are thus observed in one being, and have, according to the individual's assertions, been satisfied.

INFLUENCE OF DIET UPON THE PROPORTION OF THE WHITE BLOOD-GLOBULES.—Wilbouchevich concludes as the result of several observations upon anæmic subjects that "a purely vegetable diet has an evident effect upon the proportion of the white blood-globules," increasing them from the normal proportion of one to six hundred red globules to one to sixty-six and one to one hundred and thirty-eight.—*Le Progrès Médical*, June 20.

UMBILICAL GONORRHEA.—A unique case of this singular malady is recorded in the *Gazzetta Medica Italiana*, from the *Giorn. Ital. delle Mal. Ven.* It occurred in a youth of 19, already laboring under ordinary gonorrhœa, and doubtless ensued from the contact of matter, and was removed by astringent solutions of the acetate of lead and sulphate of zinc.

NOTES AND QUERIES.

TO THE EDITOR OF THE PHILADELPHIA MEDICAL TIMES:

DEAR SIR,—The *Times* of August 29 contains an editorial entitled "Wanted,—Leaders for a New Crusade," in which I have been much interested, not only in the main point of the article, but in the side-issues raised "in passing."

Among them, the statement that "the time for the discussion of the subject of 'women-doctors' has gone by," that "the movement will stand or fall by its results before the *lay public*," seems to me a just and true one. The objection implied, rather than avowed, in your opening paragraph, viz., "Antipathy to the hard-featured, loud-tongued, masculine woman, fitted by nature for the platform and the hustings," is greatly weakened by the admission, also implied, in connection with the advocacy of female pharmacists. "No nightmare of Mrs. Partington's sweeping his sex from the old fields of labor breaks his rest; no vision of displacement haunts his day." Do the objections to "women-doctors," among those who have so long held "undisputed possession" of the labors and emoluments of the medical profession, rest upon what is believed to be their natural unfitness, or is it a question of rivalry and fear of being swept from the field, as the statements above quoted would seem to indicate?

The danger of a "square peg" forcing a round one from its occupancy of a "round hole" can never be imminent; in short, these various lines of argument prove too much, and "the conviction that woman was unfitted by nature for the positions into which she was being forced" does not seem to refer to the same woman who is "*fitted by nature* for the platform and the hustings."

I must confess to having laid down the article with a sense of confusion, perhaps due to the fact of not having been endowed by nature with "the coolest of heads and the calmest of nerves." However, having read other editorials from the same pen with great satisfaction, and with no disturbance of mental balance, I am convinced that the difficulty with the one under discussion is inherent in the subject,—a bad cause necessarily rendering a good argument impossible.

The association of ideas found in your allusion to "free love" seems to me an unfair one: as a medical woman, I protest against it. That a few of both men and women are found so lost to the feelings of true manhood and womanhood as to advocate the doctrine spoken of, must be a grief to all lovers of good order and morality. But women who are working quietly under the protection and warrant of a regularly-chartered institution, whose curriculum of study will stand comparison with that of any of the leading medical institutions of the land, are not to be even remotely associated, in spirit and motive, with the social "Bohemians" who hang upon the outskirts of "the extreme woman's-rights movement," the vitality of which you recognize; and, while you express a true appreciation of the causes of this vitality, I believe there is an element in it which you fail to recognize, viz., a determination on the part of woman to find food for the intellectual hunger which is her natural birth-right, and "to exercise the powers with which she has been endowed, in accordance with her own convictions and feelings."

Your want of faith in "the general adaptability of the sex to the calling of the physician" has a large foundation in fact, looking at the profession exclusively upon the side of its labors, its exposures, and its demands upon the physical and mental powers generally. But there is another side of medical professional life, often ignored in the discussion of this question. There is, if I mistake not, as frequent demand upon the physician for patience, gentleness, charitable judgment, and warm sympathy with suffering, for the insight which comes through those qualities generally conceded pre-eminently to woman, as for the sterner traits justly attributed to man. Human nature includes the two phases, male and female; and I believe that the medical profession more perhaps than any other, certainly not less than the long-conceded fields of teaching, literature, and art, has room for both men and women; and, while a large part of its work may undoubtedly be done equally well by either, there is much in it that neither can do as successfully as the other,—a place where each may sleep "the sleep of undisputed possession, haunted by no vision of displacement" or "nightmare of Mrs. Partington's broom."

Your suggestion of the profession of pharmacy as suited to women strikes me favorably,—more so, by far, than the reasons assigned for it, viz., that it requires "no cool head and calm nerves," "no clear judgment," "no physical powers to bear active toil and exposure," and only a fair measure of intelligence, for its successful prosecution. The "male pharmacist" will hardly cry, "Mawsh Awlaw! God be praised!" as he reads; and the implied distrust of the purity of the motives of medical women can hardly fail to suggest another view of the matter to every candid mind. The fact that women have sought the more arduous duties of the medical profession before making any attempt in the direction of one

which imposes less self-denial and hardship while offering equal pecuniary rewards, is evidence that they have been impelled by a higher motive than mere improvement of their own condition at the least possible expense of exertion and responsibility,—that the step, in fact, has been taken in response to a demand of society for their services in departments of the profession which cannot be as suitably filled by men. Your proposition, nevertheless, is a good one; and many women who do not feel like assuming the responsibilities and anxieties of the physician's life would find in the profession of pharmacy an agreeable outlet for their energies, and a means of securing comfortable fortunes. I am reminded, however, of the farmer whose judgment in a certain case depended upon the question whether it was his own or his neighbor's ox that had been gored. The pharmacists evidently take a different view of the matter from the one you advocate. Several women have applied for admission to the Philadelphia College of Pharmacy without success. One of them, compelled to look in more liberal New York for what was refused her here, expects to graduate there next spring. Another, after seeking the necessary apprenticeship of numerous druggists in this city, who were all willing, and even anxious, that some other, *other* druggist should receive her, was finally rewarded for her perseverance by finding a man with a soul large enough for the emergency, who admitted her to his laboratory. Though the most scrupulously exact and careful of druggists, he finds her work satisfactory, and exhibits her tinctures and ointments as triumphs of the art. The corporators of the "Woman's Medical College" of this city look forward to a School of Pharmacy in connection with the medical school, as part of a plan for enlarging the opportunities for women. The new college building, to be completed in February next, will have accommodations for such a school, also for a department of dentistry.

Thus, some of the obstructions to "new avenues for suitable employment for women" are gradually disappearing, and I trust that the time so long talked of as "not far distant" is really near, when women, seeking admission to the various colleges and universities, instead of being cordially invited to "apply next door," will hear the more welcome summons to "walk in" and accept the "freedom" of the institution.

In all seriousness, I believe that there can be no real conflict of interests between men and women in the medical or any other profession, or in any department of labor whatever, since there is a mutual dependence of each upon the other, bringing mutual good; nor can either be superior to the other in any true and large sense, for both are but

"Parts and proportions of a wondrous whole."

And I think that I speak for the women of the profession in saying that it is not with them a question of equality with men,—above all, not a question of rivalry with men,—but it is the *vital* question of *individual* privilege and *individual* development of such satisfying education as shall secure to themselves enlarged activities, with the emoluments naturally accruing therefrom, as well as a question of increased opportunities for serving humanity, especially among the weak and suffering of their own sex. Could those who doubt the expediency of the admission of women to the medical profession have an opportunity of seeing our students at their work; could they witness for themselves their earnest pursuit of knowledge for its own sake, their eager search for truth among conflicting testimonies upon medical questions, their brave exertions in overcoming a natural repugnance to some of the details of the study, for the sake of accuracy and in the cause of scientific investigation, I am confident that, though prejudice might not yield to a feeling of positive admiration, at least a sense of justice would impel them to the removal of every obstacle in the way of the honest endeavor of those who, in the language of one whose professional life, not long since ended, is the special heritage of every earnest medical woman, hold themselves "accountable to God for the use of the powers which He has given them;" who believe that "their work is established in the fitness of things and in the necessities of society, and that the movement belongs to the 'revolutions which never go backward.'"

FRANCES EMILY WHITE, M.D.

[The editor of the *Times* feels that an apology is required for the occupation of so much space by so long a letter upon a subject which it has already been stated is not in a stage for profitable discussion. The letter was admitted partly because it is well written, although overlengthy, but largely because, if it and the other letters of like import but less ability received upon the same topic were declined, the accusation would be made, or might be made, that the *Times* refused to let both sides of the question be heard. We do not propose to be drawn into any discussion of the merits and demerits of women-doctors, but we certainly may be allowed to remark that all our fair critics show a "confusion" of thought about our editorial which is exceeding strange. We never said or implied that women-doctors were addicted to "free love." The plan of the editorial was, in a few words, as follows:—The extreme woman's-rights

movement has vitality, although repugnant to most men and allied to vile practices, because underlying it, not forming part of it, is the right of women to better employment,—a right which all good men acknowledge. The opposition to women-doctors [in so far as it was sincere, for, of course, it was founded on mixed motives] rested on the idea that they are not fitted for the calling, about which there is room for difference of opinion; but concerning pharmacy no such room is apparent.—Probably the subject touches too closely the feelings of those immediately concerned to allow their reasoning powers a fair chance, and hence the many ghosts of inferences which rise; otherwise the logical acumen of our critics must be very trifling. In regard to the sincerity of those who opposed the "women-doctors" movement some years ago in this city, we may state that with scarcely an exception the leaders were men who, from age, position, or other circumstances, had no possible interest at stake.]

EXON.—Philadelphia is so far behind the times as not to have the employment of medical assistants, as a general thing. In regard to getting into private practice, we have only one item of advice to offer, namely, *avoid* Philadelphia. Unless you can find some established practitioner to help, we know of no other way than to select some locality not overcrowded with men of ability, open an office, and do your best. It is possible that, by advertising, a position as assistant might be obtained in some part of the country.

OBITUARY.

WARREN.—In Cairo, Egypt, on the 27th day of June last, William Christian, aged eleven months and fifteen days, the only son of Dr. Edward Warren and Mrs. Elizabeth C. Warren.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM SEPTEMBER 8 TO SEPTEMBER 14, 1874, INCLUSIVE.

ABADIE, E. H., SURGEON.—Relieved from duty in Military Division of the Atlantic, to proceed to St. Louis, Missouri, and await orders. S. O. 200, A. G. O., September 11, 1874.

SUMMERS, JOHN E., SURGEON.—To report to Commanding General, Department of the Platte, for assignment to duty as Medical Director of that Department. S. O. 200, c. s., A. G. O.

SMITH, J. R., SURGEON.—Assigned to duty as Post-Surgeon at Fort Monroe, Virginia. S. O. 200, c. s., A. G. O.

WRIGHT, J. P., SURGEON.—Assigned to duty as Chief Medical Officer, District of New Mexico. S. O. 96, District of New Mexico, September 7, 1874.

STORROW, S. A., ASSISTANT-SURGEON.—To report in person to the Commanding General, Department of California, for assignment to duty. S. O. 200, c. s., A. G. O.

NOTSON, WILLIAM H., ASSISTANT-SURGEON.—Ordered to New York City for examination for promotion before the Army Medical Board, and at its conclusion to report to the Commanding General, Department of the Platte, for assignment. S. O. 200, c. s., A. G. O.

WILLIAMS, J. W., ASSISTANT-SURGEON.—Assigned to duty as Post-Surgeon at Fort Rice, Dakota Territory. S. O. 193, Department of Dakota, September 5, 1874.

KINSMAN, J. H., ASSISTANT-SURGEON.—Granted leave of absence for one month, with permission to apply for an extension of five months. S. O. 189, Department of Dakota, August 31, 1874.

BARTHOLOMEW, JOHN H., ASSISTANT-SURGEON.—Ordered to New York City for examination for promotion before the Army Medical Board, and at its conclusion to report to the Commanding General, Department of the Columbia, for assignment. S. O. 200, c. s., A. G. O.

CARVALLO, C., ASSISTANT-SURGEON.—Ordered to New York City for examination for promotion before the Army Medical Board, and at its conclusion to report to the Commanding General, Department of the Missouri, for assignment. S. O. 200, c. s., A. G. O.

LAUDERDALE, J. V., ASSISTANT-SURGEON.—Assigned to duty at Fort Wingate, New Mexico. S. O. 143, Department of the Missouri, September 10, 1874.

LORING, L. Y., ASSISTANT-SURGEON.—To accompany Battalion of 8th Infantry to Fort Yuma, California, on steamer which leaves September 5. S. O. 100, Military Division of the Pacific, August 31, 1874.

ELBREY, F. W., ASSISTANT-SURGEON.—Ordered to New York City for examination for promotion before the Army Medical Board, and at its conclusion to report by letter to the Surgeon-General. S. O. 200, c. s., A. G. O.

HALL, J. D., ASSISTANT-SURGEON.—Assigned to duty as Post-Surgeon at Fort Benton, M. T. S. O. 193, c. s., Department of Dakota.

SATURDAY, SEPTEMBER 26, 1874.

ORIGINAL COMMUNICATIONS.

POISONING BY CARBOLIC ACID.

BY W. H. WINSLOW, M.D.,
Baltimore.

A MAN, æt. 48 years, of most hardy constitution, took before breakfast, by mistake, about five grains of crystallized carbolic acid, dissolved in f3ij of water. He immediately experienced a burning sensation in the throat and stomach, much vertigo and nausea, with retching, but could not vomit. He looked pale, had hyperæmia of the fauces, a pulse of 90 per minute, and said he felt cold and nervous. He was given a tumblerful of fresh lime-water, and an emetic of tartrate of antimony and potassium and pulv. ipecac. No result followed. The nausea and vertigo continued, but the patient, having recovered from his fright, went to his daily labor. Symptoms continued about the same till 2 P.M., eight hours after the accident, the giddiness interfering somewhat with his working, and the nausea preventing him from eating his dinner. Free emesis then took place, which ameliorated his nausea, but the burning in the gastric region and the vertiginous trouble persisted till the following day. From the smallness of the dose and the rapid action of the drug, it is evident that the symptoms were caused by peripheral irritation of the vagi and the sympathetic nerve fibres. This affected the heart by reflex action, as the pulse did not decline till perfect recovery. The acid could not have injured the mucous membrane much, if any, and though by irritation nausea was excited, yet its anæsthetic effects were clearly demonstrated in the stomach's resistance for many hours to the large emetic given, which acted freely when time had abated the anæsthesia.

Among the different qualities of carbolic acid manufactured, none is more disagreeable and acrid than Calvert's No. 4. It is a reddish, oily, pretty fluid, of most disgusting odor, put up in blue bottles and having printed directions for use, and was the preparation most commonly used for disinfecting purposes during the recent epidemic of variola. Many families in my neighborhood kept receptacles of this acid exposed about the house, and one lady had an uncorked bottle, containing about a fluidounce, suspended to a chandelier in the dining-room. During house-cleaning time this bottle was taken down and placed upon the table, where a hearty two-year-old child found it, about 10 A.M., and swallowed about f3ij of the contents. He immediately dropped the bottle, screamed, and fell upon the floor. His mother, taking in everything at a glance, picked him up and ran into an apothecary-store next door. The person in attendance forced the patient to drink about f3iv of lime-water and f3i of olive-oil, when insensibility supervened. I saw him ten minutes afterwards. He was in profound coma, with general sensibility totally abolished. The surface was pallid, and bedewed with copious perspira-

tion. The limbs were flaccid, the eyelids were closed, a bluish, pinched expression rested about the lips and nose, the alæ moved excessively, the lower jaw was dropped, and a white, frothy saliva, which filled the fauces, ran freely from the oral cavity. The pulse was soft, feeble, and irregular, at 160 a minute; the respiration was labored, irregularly jerking, stertorous, and hissing, 70 times a minute; the mucous membrane of the fauces and tongue was white, and patchy with marginal streaks of capillary injection; the pupils were widely dilated, and irresponsive to light. He was not able to swallow a few drops of milk placed upon the base of the tongue: therefore the latter was pulled well forward, and a teaspoonful of olive-oil was emptied into the pharynx. This was immediately ejected, with much frothy mucus, and an alarming suffocative attack followed. This dose was repeated several times, with like result. An emetic was rejected, and apomorphia could not be obtained. Occasional shudders ran over his body, followed by slight clonic convulsions of the muscles and most alarming and prolonged spasms of the glottis, during which cyanosis became very deep and life seemed about to terminate. Any attempt to administer anything per ore, or to clear the throat of mucus by a cloth, wet with iced port-wine, upon the finger, excited the distressing and dangerous spasm of the glottis and a general convulsion. The condition was distinctly tetanoid, and squeezing the hand firmly, fanning him violently, and applying a cold cloth to his head, each separately caused an attack of the convulsions. Upon severe irritation (the prick of a pin) the same result occurred; but no other signs of sensibility could be elicited; thus proving that the poison more profoundly affected the sensorium, or the whole cerebrum, than it did the spinal axis.

Considering all the circumstances, it was not deemed advisable to try to use the stomach-pump. Turpentine injections were administered, large mustard-plasters applied over the trunk and inferior extremities, and the throat was cleared by a cloth over the finger. So alarming and prolonged was one of the suffocative attacks, and so deeply cyanosed was the surface, that I thought laryngotomy might afford some relief; but, my friend Dr. Cleeman, who gave me the benefit of his mature judgment, not agreeing, and the spasm yielding just when it seemed life must go, the idea was abandoned.

The poor child lay in this unsatisfactory condition, with no apparent improvement, for two and a half hours. Occasionally the perspiration would increase greatly in quantity upon the face and breast, and then evaporate, to be renewed again in drops, which grew under the eye. Soon after the application of a fresh sinapism to the abdomen, he slowly returned to consciousness, pushed and pulled at the plaster, and called "mamma" faintly. During the next few hours he took considerable powdered chalk and sugar, white of egg, iced port-wine and milk, and had a most ravenous appetite.

At 6 P.M., eight hours after the accident, he ate

a large slice of bread-and-sugar, and talked intelligently to the anxious ones around. The profuse salivation had disappeared; the pulse was soft, full, but jerky, at 160 a minute; the respiration was 55, dry and whistling, and the child was restless and of fitful temper. Urine and fæces, without any mucus or blood, were voided at 7 P.M., and the only danger apprehended was that of extension of the existing laryngitis. He was kept in a steamed atmosphere, and during the evening was apparently comfortable. There was no fever, the skin was moist and cool, respiration softer, at 48 a minute, and pulse at 150, with nothing remarkable in his general appearance.

Up to 11 P.M. he had occasional naps of disturbed sleep, then would lie with eyes half open, mumbling. When his mother put him into bed, he said, distinctly, but hoarsely, "I want a drink of ice-water." From this time to 4 A.M. he had some sleep, but was restless, and moved about often in the bed. At this time the face was pale, and pupils normal; the pulse and respiration were unchanged, except that the glottis was kept closed after inspiration, until the air apparently forced it open with an audible grunt. There was no tympany or tenderness of the abdomen, and no anæsthesia or paralysis of motion. There was no attempt to vomit, from first to last. A large fecal evacuation, containing mucus and a curdy material (undigested milk) without blood, had occurred at 3.15. The urine was heavy, but normal.

After 4 o'clock in the morning, a change took place. The patient's skin became dry, and had the pungent heat so characteristic of scarlatina. He became restless, whined and moaned, and talked hoarsely and incoherently, shrank from the light, and pulled at his head with both hands, as if to remove some offending object. The pulse rose to 170, and the respiration to 50 in a minute. His movements were peculiar and remarkable. He would crawl upon his hands and knees from one side to the other of the bed, then up to the pillow, where he would lie a moment, then he would move down in the bed and pull the clothes over him, only to kick them off and to begin his journeying again; all the time moaning and muttering unintelligibly. The respiration was now altered in rhythm, becoming more irregular; a few mucous râles could be heard in the lungs, but there was no change in the rough, hissing sounds as the air passed the glottis, and only slight obstruction to the respiration. The eyes moved from side to side and upwards incessantly. No squints, twitching of the facial muscles, or grinding of the teeth occurred. Isolated muscles jerked spasmodically, and tendons sprang into prominence and then disappeared. The thumbs were flexed into the palms.

In spite of active measures adopted to combat a supposed meningitis, the symptoms grew rapidly worse. The respirations became shallow and more irregular; the pulse rose beyond counting; the eyes became quiet and glazed, the limbs motionless, and coma profound. He died quietly from failure of the respiration, the heart beating some moments longer, at 6 A.M.,—twenty hours after

the ingestion of the poison. No post-mortem was permitted.

In Dr. H. C. Wood's work on Therapeutics, *Materia Medica*, etc., carbolic acid is said "to produce muscular weakness primarily, then tremblings and restlessness, and finally convulsions; which latter are epileptiform, and originate at the base of the brain." This little patient first fell down. Was it from muscular weakness, or shock? I think from both. Dr. King's case fell down immediately, never to rise again. The shock would, of course, cause muscular weakness. Tremblings and restlessness would necessarily accompany a moderate shock, though none were noticed in this child's early condition. Convulsions followed very soon, and were prolonged and severe. I believe it is now settled that from carbolic acid poisoning the convulsions are of cerebral, not spinal, origin. The rapid pulse and respiration are accounted for by the peripheric irritation of the pneumogastric nerves, and the profuse diaphoresis by the vaso-motor paralysis.

The terrible shock of the morning evidently produced no serious lesion of the nerve-centres, or effusion within the cranium. Perforation or severe inflammation of the stomach did not take place. There was not any serious obstruction to respiration. Up to 4 A.M. there were no symptoms to indicate danger, more than when the patient first recovered consciousness,—certainly no signs of progressive effusion. If there was meningitis finally, it seemed too mild to terminate life so soon. In the first period there was shock, then a prolonged and extraordinary term of quiescence, then a second explosion, which terminated life. Some cases are said to die of "secondary shock." I believe that to have been one, at least, of the causes of death in this case. The long period of repose was due to the drug's anæsthetic properties, but as soon as that effect had passed away a "secondary shock" occurred, which produced vaso-motor paralysis, cerebral effusion, and death.

ON THE TREATMENT OF ASCARIS OXYURIS.

BY SAMUEL S. BOND, M.D.,

Washington, D.C.

ALTHOUGH no single drug, or combination of drugs, can be reckoned as a specific for all varieties of intestinal worms, yet there are remedies whose action is almost that of a specific, as, for instance, the combination recently published in the *Druggist's Circular* by Mr. Schafhirt, and since copied into most of the medical journals, for the entire destruction of the tapeworm, and the oil of male fern, turpentine, and more especially santonin, for the lumbricoides; and though each of these remedies sometimes fails of the object, nevertheless we generally succeed in expelling the tormentors by the administration of one, where another has previously proved ineffectual. I think that in the case of lumbricoides, santonin seldom fails in its action.

I use it almost exclusively, and have greater confidence in it than in any other single remedy; but, while this and the many other remedies are so generally successful in expelling the larger worms which infest the small intestines, there are no remedies laid down in our text-books that we can rely upon for permanent relief from the annoyance of those terrible tormentors, the oxyuris.

Much has been written and many investigations have been made regarding these pests, and yet, either from a mistaken theory in regard to their exact residence in the intestinal canal, or an improper mode of application of the proper remedy, or inability to select the proper remedy, real cures are less often effected and less confidently looked for in this than in any other variety of intestinal worms.

The employment of bitter injections, especially quassia and aloes, with the administration of senna and sulphate of magnesium, separately or combined, has, in most cases, afforded relief for a limited period, but has utterly failed to cure the affection permanently.

Very recent writers adhere to the long-entertained opinion that the oxyuris infests only the lower portion of the large intestine. But a single writer, so far as I have been able to ascertain (Dr. Cobbold), locates the residence, or, as he expresses it, the head-quarters, of these worms high up in the colon, even the cæcum. I am inclined to accept this theory, for, as the doctor says, "if they were confined to the rectum the injections would afford permanent relief." Such we know, however, is not the case; partial relief only is obtained for a limited period, which period I take to be merely the time required for the oxyuris from above to migrate to the lower bowel in quantities sufficient to call attention to their presence there.

While in the drug-store of Mr. Schafhirt, several months ago, he remarked to me that the compound syrup of asarum was found in a great number of my prescriptions, and inquired if I had ever noticed its effects upon the oxyuris, stating at the same time that he had accidentally discovered it to be an excellent remedy for them.

At that time I had never noticed the effect he claimed it produced, and I observed that the fact, if fact it was, was entirely novel to me.

I had been a sufferer myself from these pests for many years, but for a long time had ceased to use remedies for the purpose of trying to get rid of them, having failed to obtain permanent relief so frequently before. Bearing in mind the remarks of the druggist, I recollected that for several months past I had not been annoyed as usual by these worms, and that about the time of their disappearance I had used a considerable quantity of the compound syrup of asarum in mixtures I was then taking for a cough. This disposed me to consider the subject as worthy of future observation and investigation.

Having among my families many children and a few adults annoyed with these worms, I resolved to test the remedy and give the drug a fair and thorough trial in a number of cases. The results of my experiments have proved far more satisfactory

and gratifying than I had anticipated, and I am thoroughly convinced that it is a valuable and reliable remedy, far more so than any other drug I have ever used for the same purpose, exhibiting in its action an almost specific effect.

I have used it now for many months, and with very decided benefit in many cases, the worms so far having failed to reappear. With quite young children I usually administer it in the form of the compound syrup, as prepared from the non-official formula of Dr. C., while for older children and adults I use a strong infusion, or give it in substance, in some cases the patients chewing it as they would liquorice-root, as much as half an ounce daily.

I usually commence the treatment by evacuating the intestinal canal by means of a cathartic, and generally follow with senna, using also nightly, for two successive nights, injections of a cold infusion of quassia, after which the internal use of the asarum for a week or ten days usually effects a cure.

Should the remedy prove as successful in the hands of others, and its anthelmintic character be established, it will supply a want which has long existed, being so devoid of danger in its nature that it can be freely administered to persons of every age and condition, and its cheapness bringing it within the means of the most indigent, while its pleasant aromatic taste renders it acceptable to children, when more nauseating medicines would be with much difficulty swallowed.

This experience is given to the profession in the hope that others may be induced to test the subject and state the result through the medical press.

ON THE MODE OF APPLYING ESMARCH'S APPARATUS, AND A FURTHER MODIFICATION OF IT.

BY W. W. KEEN, M.D.

LANGENBECK* and Mears† having reported some cases of paralysis from the use of Esmarch's apparatus, I desire to call attention to the fact that the bandage, and especially the tubing, if used, is generally applied *too tightly*. This is to be attributed to the facts that we all desire to be on the safe side, and *surely* to arrest the hemorrhage, and also that errors attend the earlier use of every apparatus,—errors which time and experience correct. In this case, in the desire to arrest the bleeding we may easily go too far, and, by applying the bandage too tightly, produce paralysis. One indication will show us whether the bandage is tight enough,—viz., if the skin remains blanched. It will be seen at once that if the arteries are not compressed the apparatus will act as the fillet in the ordinary operation of bleeding,—producing a dusky skin and turgid veins. Feeling for the pulsation of the arteries is not necessary, for the condition of the skin is a better indication.

The loosest application of the bandage that will

* Amer. Jour. Med. Sci., Jan. 1874, pp. 551-3.
† Phila. Med. Times, Aug. 15, 1874.

blanch the skin and keep it so is the best; and, in fact, I have found that with almost every new case I have used it more and more loosely.

Even if the bandage has been applied properly, when we come to apply the tubing the tendency and the temptation are to too great tightness. The tubing need not and ought not to be any more tightly applied than the bandage itself. Its narrowness and greater rigidity expose the nerves to greater risk of mechanical injury; and hence the modification proposed by Langenbeck and Mears, to substitute a second bandage narrower than the first, is an excellent one. But even with this, as Dr. Mears has shown, the pressure may be too tightly applied.

The broader the band, the more diffused is the pressure and the less is the danger, even if the pressure be too great; and it occurred to me that the apparatus could be simplified still further and at the same time made safer by using *only* the first broad bandage (two and a half inches wide). Accordingly, in using the apparatus, a few days since, for the removal of a fragment of iron from the lower part of the fore-arm of a muscular man, I tried this method, as follows, and with complete satisfaction. I applied the bandage nearly up to the elbow, using but little more force than is needed in ordinary bandaging; then taking hold of the lower end of the bandage I unwound it from below, but little force being required to pull one turn from beneath the next; and when it was all unwound except the last three turns I simply tied the ends together. The skin remained blanched; the operation was absolutely bloodless till the bandage was removed, although the arteries were so deep in a muscular fore-arm and the bandage not tightly wound. No paralysis followed. In these operations for the extraction of foreign bodies, as Brandis has pointed out, the method finds one of its happiest applications.

RESECTION OF THE TIBIA AND FIBULA AT THE JUNCTION OF THE MIDDLE AND LOWER THIRDS.

BY A. TREGO SHERTZER, M.D.,

Baltimore, Md.

ON the 23d of March last, I was summoned to see Mrs. H., aged 51, who had been run over by a large, heavily-loaded lager-beer wagon, producing a compound comminuted fracture of the right leg. Before I saw her, two physicians had seen her and advised amputation, and I was sent for to perform the operation. Upon a careful examination, I decided to resect, and sent for my friends Drs. Andre-Cathell and Taylor, who kindly assisted me in the operation. After the patient was chloroformed, I made a longitudinal incision, seven inches in length, along the outer side of the anterior portion of the tibia, and removed forty-seven fragments of bone, and, with a strong pair of bone-forceps, I cut off the four ends of the broken bones, leaving a space of fully three inches in which there was not a particle of bone. After cleansing the wound, I united it with silver sutures, using no adhesive plaster whatever, and had it firmly packed in a bran-

box, which I had made for the purpose, as follows. The outer and inner sides were made of thin board, extending from the upper portion of the thigh to the foot, with a slanting foot-board, to which I secured the foot, while the bottom was firmly closed with canvas; three narrow strips screwed over the top—one at each end and one in the middle—held it firmly together. The limb being placed in the box and well packed with bran, it could not move, and the bran could easily be removed and replaced as it became soiled, while at the same time the patient could sit up in bed. After five months she was able to walk on crutches, and is now able to walk alone, the limb being nearly one inch shorter than the other one. The wound healed without difficulty, under a dressing of sweet oil, glycerin, and carbolic acid. Not a single piece of bone came away after the operation. Throughout, general tonics were exhibited.

NOTES OF HOSPITAL PRACTICE.

UNIVERSITY OF PENNSYLVANIA.

SERVICE OF DR. H. C. WOOD.

Reported by Dr. LOUIS STARR, Chief Assistant.

AMENORRHOEA—HYSTERICAL PARALYSIS AND CHOREA —CURE.

A. F., aged 15, first applied for treatment at the dispensary on June 28, 1873. There is no history of any form of nervous disorder in her family, and she enjoyed good health herself until five years ago, when she had an attack of chorea, from which, however, she recovered in four or five months. After this, although able to attend to her studies and to do light work, she was weak, and slightly hysterical.

Menstruation began early in the spring of 1872, and was performed without pain and at regular intervals until December of the same year, when it stopped entirely. The cessation of the menstrual flow was followed by great prostration and emaciation, and by partial motor paralysis of the right arm and leg. When the patient came under observation she was very anæmic, and there was considerable loss of power in both the arm and the leg. The former was most affected, and was slightly smaller than its fellow; flexion and extension of the hand and fingers were possible, but these movements were executed sluggishly, and there was no strength in the grasp of the hand; the muscles of the upper arm and of the shoulder were not involved. There was some dragging of the right foot in walking, and a sensation of weakness in the leg from the knee down. The sensibility of the affected muscles to the faradic current was not markedly different from that of the other side. Electro-contraction was also normal.

She was placed upon the following mixture:

R Tr. ferri chloridi, f3iii;
Tr. cantharidis, ℥xxxvi;
Tr. aloës, f3ii;
Tr. guaiac. ammon., f3iiss;
Syr. simp., q. s. ad f3vi.—M.

Of this she was directed to take a tablespoonful thrice daily; at the same time a moderately strong faradic current was applied to the leg, fore-arm, and hand, for ten minutes, three times a week.

Under this treatment she began to improve, and on August 30 her appetite and general strength were much

better, the menstrual flow was re-established, and the right leg had regained its power so that she was able to walk without difficulty. The arm, though better, was still quite weak, and she complained of choreic twitchings of the index and middle fingers when sewing or holding light objects; these varied in severity, and when most severe were accompanied by similar movements in the muscles of the face. Instead of the above mixture, ext. cimicifugæ fld. was prescribed, to be taken at first in doses of f3i three times daily and gradually increased to f3iss; faradization of the arm and hand being still kept up.

After two weeks the cimicifuga was suspended, on account of the severe headache and giddiness which it produced, and she was ordered gtt. v of liq. potass. arsen. with gtt. xv of tr. ferri chlor., three times a day. Soon after this combination was adopted, the choreic movements of the fingers and face, which had apparently been unaffected by the cimicifuga, began to decrease; the strength of the arm also seemed to improve more rapidly than before.

From this time (September 16, 1873) up to the date of discharge (November 1, 1873) the favorable progress of the case was uninterrupted, and no change was made in the treatment.

She returned, according to request, three weeks afterwards, and reported herself entirely well; during the interval all electrical treatment had been suspended and no medicine whatever had been taken.

TRANSLATIONS.

THE FORMATION OF VESICAL CALCULI.—Statements of Neubaur and Vogel, that the urine of carnivora presents no essential difference from that of man, and observation of a case in which a needle thrust into the bladder through the perineum became the nucleus of a calculus, induced Studenski (*Inaugural Diss.*, 1873) to undertake a series of experiments upon dogs, with the view of establishing the influence of foreign bodies in producing lithiasis. Bitches were preferred by him for his experiments, because examinations with the catheter are more easily made upon them than upon dogs, and he introduced into their bladders by the high operation for stone various objects, such as beads of glass or gutta-percha, leaden balls, needles, etc. All of these objects except the last-named had to be of a size at least as large as a hazel-nut, to prevent their entrance into the urethra, an accident which was followed by the death of the animal. After the operation, the treatment pursued was of four kinds: 1, customary food, as meat, bouillon, bread, etc.; 2, customary food with the addition of lactic acid; 3, the same sorts of food, to which oxalic acid had been added; and 4, the use of large quantities of water containing lime. The results of the experiments proved that the same principal forms of urinary sediment are met with in dogs as in men, but that a very long time is needed for their formation. In the case of a dog which was fed with the diet of the first kind, and was killed a year after the introduction of a glass ball into the bladder, this foreign body was found to be covered with two layers of the phosphate and oxalate of lime, but they had only attained the thickness of ordinary writing-paper. In the case of an animal which was fed in accordance with the second diet-list, and which was killed four months after being operated on, no deposit was found, except in the perforation of the glass ball. The deposit upon leaden balls taken from the bladders of animals of the third series was also very slight in quantity.

The results obtained in the fourth series were of a more positive character: the animals for the most part died in a comparatively short time, but examination of the foreign bodies in their bladders showed but a slight urinary deposit upon them.

Attention is directed to the fact that no oxalate of lime was found in the urine of those animals which were fed with oxalic acid in considerable quantities, but this salt was found in the deposits from the urine of one of the animals fed upon ordinary diet. In all cases in which the introduction of the foreign body was followed by catarrhal inflammation of the bladder and alkaline fermentation of the urine, sediments of the earthy phosphates were quickly formed. The addition of lime-salts to the diet seemed to exert a marked influence upon the formation of the phosphate of lime, even when the vesical mucous membrane remained sound. W. A.

PERINEPHRITIC ABSCESS.—Schwartz (*La France Médicale*, 1874, No. 49), in describing a case, calls attention to the difficulties attending the diagnosis of perinephritic abscess. These are principally due to the deep seat of the affection and to the slight local trouble which it occasions as compared with the gravity of the constitutional involvement. The development of a fluctuating tumor in the lumbar region is the most characteristic symptom, and often a long time elapses before this is met with. In the beginning of the attack, the febrile symptoms are similar to those met with in ileotyphus, while later they resemble those of remittent fever. The patients lose flesh rapidly, and their cachectic earthy complexion may lead to the diagnosis of the disease. The pus, as a rule, remains confined to the place in which it was formed, and comes to the surface in the lumbar region, but may possibly, when the opening of the abscess is too long deferred, or when the process manifests from the start a tendency to travel, first make its appearance above or below Poupart's ligament or along the great vessels of the thigh. The pus formed in a perinephritic abscess may also pass into the bladder, the vagina, or the intestine, or, still more rarely, perforate and enter the sac of the peritoneum. Evacuation through the bronchial tubes has also been observed, and the entrance of the pus into the pleural cavity has led to pleurisy or pneumonia. The prognosis in this affection varies according to the etiology of the attack in question. Perinephritis can be spontaneous or traumatic in its origin, can be due to transference of inflammatory action from neighboring organs, or finally it may arise in the course of infectious diseases of a severe type. When the abscess is promptly opened, the prognosis of the first two varieties enumerated above is good, that of the other forms is grave. The only method of opening abscesses of this character which can be recommended is that of incision, followed by drainage of the wound. W. A.

VISCERAL RHEUMATISM.—The *Gazette Hebdomadaire*, Aug. 7, contains some notes of a case of rheumatism coming under the care of Dr. Blachez, which presented a very unusual complication,—namely, peritonitis. The patient, a young and healthy woman, had been under treatment for some weeks, suffering from an attack of ordinary acute articular rheumatism. The case was complicated by endo-pericarditis and pleurisy, but the patient did well, and was apparently about to enter upon the stage of convalescence, when, almost suddenly, one night, she was attacked by vomiting and severe abdominal pain, the belly became tympanitic, the pulse rapid and small, and there was every symptom of acute peritonitis. Soon after, delirium set in, and the patient refused almost absolutely to take nourishment, having to be nourished by injection. After lingering in this condition about a week, the patient died. Unfortunately, no post-mortem examination could be obtained.

M. Blachez remarks upon the rarity of this peritoneal complication, which he has never observed in any previous case.

As regards its existence there could be no doubt. The pain, distention, and tympany of the abdomen, the stercoraceous vomiting, the alteration of expression, the pinched nose, the coldness, all constituted characteristics upon the value of which it would be useless to insist. While all the serous membranes are tributary to rheumatism, the peritoneum almost always escapes. For this reason the case under consideration is almost unique. M. Blachez concludes by some remarks on the heart- and brain-complications occurring in this case, which, however, have nothing peculiar about them.

A. V. H.

NON-INOCULABILITY OF TUBERCULOSIS.—Dr. Edward Metzger read before the Académie de Médecine at a recent sitting an account of experiments performed by himself, to the number of seventy or eighty, extending over the last five years.

These experiments, made to demonstrate the non-inoculability view held by Dr. M., prove, he thinks, that phthisis is neither inoculable, virulent, nor specific. Capillary emboli, infarctions, or alveolar pneumonias, Dr. M. believes, have been mistaken for tuberculous deposits.

Dr. Villemain, he seems to think, has made serious mistakes in his methods of practising and observing the effect of the inoculation of tuberculous matter in animals. Dr. Metzger's paper was referred to a special committee.

A. V. H.

THE OCCURRENCE OF ENLARGEMENT OF THE SPLEEN IN RECENT SYPHILIS.—Dr. A. Weil (*Centralblatt für die Med. Wissenschaften*, 1874, No. 12), while noticing the fact that enlargement of the spleen is not uncommon in the later periods of syphilis, states that he has been able in three cases to establish, by palpation and percussion, enlargement of this organ in recent syphilis; indeed, while the primary induration was still present. The extent of the dulness in the direction of a line running to the axilla was from ten to twelve centimetres. In one of the cases there was present a maculated syphilide of four weeks' duration; and in both the other cases the eruption appeared three or four weeks after admission into the hospital.

In the course of an anti-syphilitic treatment, the enlargement of the spleen disappeared; and Weil sees in this a confirmation of his view that the tumor was due to syphilis. He expresses at the same time the opinion that the enlargement of the spleen in these cases is of the same significance as in typhus, intermittent, etc., i.e., a symptom of the infection of the entire mass of the blood. More extended observation will be needed before this symptom, which must be due to hyperæmia of the spleen and increase of the cellular elements of its pulp, can be of clinical importance.

W. A.

THERAPEUTIC NOTES.

TREATMENT OF SYNOVITIS OF THE KNEE-JOINT BY HOT SAND-BAGS.—M. Bergeret employs this treatment in the following manner. The knee is enveloped in raw cotton, and over this a bag containing two or three quarts of sand.

The sand should be as hot as can be borne by the hand, the bags containing it being of a size sufficient to more than envelop the entire area of the disease. They should of course be covered with a blanket or some non-conducting material, and should remain in

position until they cool. Under the influence of this application a rapid and profuse perspiration soon takes place. The hot sand-bags may be renewed several times a day, and before many days, such is Dr. B.'s experience, the fluid entirely disappears.

It is understood that this treatment is applicable only to the chronic stage of the disease; Dr. Bergeret's aphorism is, "Humid heat in the acute, dry heat during the chronic period."—*Gabler's Jour. de Thérap.*, May 10, 1874.

TREATMENT OF VULVAR PRURITUS.—Alum-lotions may be ordered, as follows:

R Alumin., 4 grammes;

Decoct. hordei, 500 grammes.—M.

Use the lotion three or four times a day.

M. Hardy frequently uses the following:

R Hydrarg. chlor. corros., 1 gramme;

Aquæ destil., 100 grammes;

Alcohol., q. s.—M.

A spoonful in a glass of warm water. Avoid rubbing the parts during its application.

In the vulvar pruritus which so frequently accompanies pregnancy, Dagon uses the following formula:

R Zinci oxidi, 4 grammes;

Sodæ boratis, 2 grammes;

Cerat. simplicis, 15 grammes;

Ol. amygd. dulcis, q. s.;

Morphiæ muriatis, 20 centigrammes.—M.

Bazin prescribes the following liniment:

R Liquor calcis, 30 grammes;

Glycerin., 30 grammes;

Ol. amygd. dulcis, 60 grammes.—M.

The following has also been recommended:

R Glycerin., 150 grammes;

Tinct. opii, 4 "

Ol. rosæ, 5 drops.—M.

—*New York Medical Journal*, from *La France Méd.*, No. 54, 1874.

APOMORPHIN AS AN EXPECTORANT.—M. Jurasz (*Gazette Hebdomadaire*, from *Centralblatt*, No. 32, 1874) suggests the use of this emetic in bronchitis, etc., in the same manner as ipecac and other nauseating expectorants are employed. His formula is as follows:

R Apomorphiæ chlorid., gr. $\frac{1}{8}$ ad $\frac{1}{2}$;

Aq. destillat., ℥iijss;

Acid. hydrochlor., gtt. v;

Syr. simplicis, ℥iv.—M.

Sig.—Tablespoonful every two hours.

Each dose contains $\frac{1}{8}$ to $\frac{1}{4}$ of chlorohydrate of apomorphia. In general, after the first few doses some little nausea is observed, but vomiting is not produced. This preparation is useful when it is desired to produce a more free discharge of the mucous secretions, or where these, as is frequently the case in bronchitis, are tenacious and not easily separated.

COMPOUND FERRUGINOUS POWDER.—

R Ferri carb., ℥i;

Valerian. rad. pulv., ℥iiss.—M.

Div. in chart. no. xxv.

Sig.—One to five a day in chlorosis complicated by neuralgia.

PILLS IN LEUCORRHOEA.—

R Cantharidis, gr. ii;

Camphoris, gr. x;

Ext. hyoscyami, gr. v.—M.

Ft. in pil. no. l.

Sig.—One or two a day in nervous leucorrhœic cases.

PHILADELPHIA MEDICAL TIMES.

A WEEKLY JOURNAL OF

MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY

J. B. LIPPINCOTT & CO.,

715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, SEPTEMBER 26, 1874.

EDITORIAL.

THE AMERICAN TEA.

GROWING along the Atlantic coast of the United States, from Virginia southward, is the *Ilex cassine*, or, as it is sometimes called, the American tea,—a plant whose leaves, mixed with those of other species of the same genus, were used by the aborigines in forming the decoction known as “yaupon,” or “black drink.” The maté of Paraguay is closely allied in its botanical relations to the plant under consideration. It is well known that this Paraguay tea contains largely of theine, and the fact that the Northern Indians used our *Ilex* very much as the aborigines of Paraguay used their *Ilex*, ought, one would think, to have attracted attention long ago to the North American plant.

During the Revolution the leaves of the *Ceanothus Americanus* were used as a substitute for the Chinese herb, and, possibly owing to this fact, some few years since a company was organized for the purpose of producing, and actually did produce, a “tea” prepared from the *Ceanothus*. Analysis showed, however, that this product contained no theine; and, although the New Jersey staple was quite extensively advertised, it soon disappeared from sight. Subsequently, we were informed by a dealer that this American tea was still manufactured, but that it was used solely for the adulteration of the genuine article. Whether or not it is still produced we do not know.

A Mr. H. M. Smith has recently made an analysis

of this “yaupon” (*The Journal of Applied Science*, September 1, 1874), and found that it contains a very large percentage of theine, besides a peculiar volatile oil having a tea-like odor. The specimen analyzed was composed in a very large proportion of twigs, yet the percentage of theine present was as great as that usually found in maté. The following table expresses the proportion in one hundred parts of the substances named:

	Yaupon.	Maté, or Paraguay tea.	Black tea, average.	Green tea, average.	Green tea.	Coffee.
		Stenhouse.	Mulder.	Mulder.	Peligot.	Payen.
Volatile oil.	0.01		0.63	0.88	0.50	0.003
Caffeine.....	0.12	0.13	0.56	0.52	6.00	1.00
Tannin.....	2.41		2.04	17.68	14.00	10.00

The yaupon leaves were a regular article of commerce among the North American Indians. The “black drink” was used by the Indians especially at their councils and tribal feasts. It was taken very strong, and in large quantities, and is said to have frequently acted as an emetic. It contained, however, besides the leaves of *Ilex cassine* those of the *Ilex vomitoria* and of other species of the genus, and it is possible that it owed to them its power of causing vomiting. Evidently, if the *Ilex cassine* possesses a persistent emetic property it will never afford a cup of tea which shall be popular with the white man. A general emesis might be a bond of misery among a council of Indians, but would hardly suit the average sippers of Bohea. Mr. Smith, however, failed to detect any emetic principle in the *Ilex cassine*, and the subject seems to demand further investigation.

DRUGGISTS' COMMISSIONS TO DOCTORS.

“THE *Evening Star* says:—The retail druggists of Chicago have taken this action:

“Whereas, The practice of paying commissions to physicians in any form is in direct opposition to the principles upon which this college was established, if not a violation of the strict wording of its code of ethics; it is therefore

“Resolved, That the maintenance of just and honorable relations between physicians and druggists or pharmacists is a matter of the highest import to our college, and we do not hesitate to condemn a system that substitutes a money consideration for the just claims of merit and education.”

“[This is apropos of our editorial of a recent issue. Now let our respectable druggists of Philadelphia follow this lead. The brave words spoken by the Northern Medical Association of Philadelphia, under a similar

provocation, some seven or eight years ago, would bear repetition and imitation by the Philadelphia County Medical Society, and all the other kindred bodies of this city.]”

The above extract is from a recent number of *The Cincinnati Medical News*. In reply, we can only state that if any regular physician in this city takes a commission from druggists he is very careful to keep his doings secret. Public medical opinion in this city certainly reprobates most earnestly such practice.

A WRITER in *The Journal of Applied Science* (September 1) states that castor-oil has so little effect on Chinese intestines that the Celestials use it habitually in cookery.

CORRESPONDENCE.

THE RECENT MEETING OF THE BRITISH MEDICAL ASSOCIATION.

NORWICH, ENGLAND, September 1, 1874.

DEAR SIR,—I had the honor of attending the dinner of the British Medical Association, in St. Andrew's Hall, on the evening of the third day of the meeting, which was a most genial and festal occasion. The grand old civic hall, that had been in ancient days a cathedral, and was adorned with portraits of local celebrities of the past, was transformed into a brilliant banqueting-saloon. There were music, and flowers, and fountains, and speech-making, both eloquent and hilarious; and, as the dining ended, a large assembly of ladies arrived and graced a platform arranged for them. The dinner-ceremonies opened with a blessing by a reverend canon, which was appropriately short, and it was followed by a most effective rendering of the majestic anthem of “God Save the Queen.” A military band played at intervals, and the peals of a trumpet pre-announced every toast.

Sir James Paget responded to the toast of “Prosperity to the British Medical Association,” and said that the body was never so prosperous, influential, and numerous in membership as at this time. He alluded to the importance of what had been presented in the special sections, and predicted the continued development of the institution. I was impressed with the evidences of the great popularity of this distinguished member of the profession, and had previously seen repeated manifestations of the profound respect and affection that are universally felt for him. In proposing the health of Mr. Southam, of Manchester, the President of the Council, Sir James awarded to him the credit of much of the efficiency of the Association.

Mr. Southam arose amidst loud manifestations of favor, and spoke of the progress of the Association during the period of twenty-eight years since the annual meeting was held in this city.

Mr. Quain, on being called for, proposed the health

of the President elect, Dr. Copeman, of Norwich, and announced him as “The foremost man in the county, who took his position as a right and in deference to what he had contributed to medical science.”

Dr. Tufnel, of Dublin, President of the Royal College of Surgeons of Ireland, and formerly of the army, responded to a toast to “The Army, the Navy, and the Auxiliary Forces,” in a speech of much enthusiasm in regard to the rights of army medical officers.

In reply to the toast of “The Visitors,” Dr. Sims, of New York, gracefully expressed his thankfulness for the welcome reception of the American guests of the Association, and disclaimed being considered a foreigner, as he was honored with membership, and had at one time resided and practised the profession in England. The evidences of respect and personal good feeling for this distinguished American surgeon were, throughout both the scientific and the social portions of the meeting, most marked, and showed the appreciation of his high character and of what he has added to one important department of surgery.

Dr. Haughton, of Dublin, made a humorous and characteristic speech, and the annual dinner concluded most happily when the ancient hall resounded to a roaring toast of “The Ladies.”

My estimate of the scientific character of the meeting is very high; and to this must be added the invaluable social influences of such a gathering of so many of the distinguished members of the profession in Great Britain, and of representatives of different nationalities abroad. As an American, I speak appreciatively of the distinguished attention and courtesy with which my countrymen were honored at this meeting. Such international representation is surely calculated to unite in the strongest sympathy the medical profession of different countries.

The occasional visits to America made by distinguished British physicians and surgeons, and the journeys undertaken every year by numbers of American medical men to Great Britain, have done much to add to the good feeling that has ever existed between the medical fraternities of the two countries. The bestowal of titled honors and distinguished social attentions on Professor Gross during his late visits to Europe have been received at home as compliments, through a representative man, to the whole profession in America. I think that I have never been introduced as an American surgeon to prominent surgeons anywhere in Europe without having kind and respectful inquiries made of me concerning Professors Gross, Pancoast, Sayre, Dr. Sims, Dr. Atlee, and a few other surgeons whose reputations have extended abroad.

I can also speak from an extended intercourse, particularly with surgeons in Europe, of their warm feeling for the American people and of a general interest in the approaching Centennial Anniversary of our nationality. Sir James Paget expressed to me his especial desire to be at the celebration in Philadelphia on the Fourth of July, 1876, and said that he would take delight in the noisy enthusiasm of the day. I have received

also expressions of such friendly tone from such distinguished surgeons as Sir Henry Thompson, Erichsen, Callender, Lister, Bryant, Hancock, Southam, Gamgee, and MacDonnell.

In a note now lying open before me from Dr. Bate-man, of Norwich, a truly good and able man, whose name is most known in America by his work on Aphasia, alluding to the recent meeting of the British Medical Association, he says, "I think it is impossible to overestimate the importance of these cosmopolitan gatherings: nothing is more calculated to consolidate the peace of the world, and to show the absurdity of resorting to physical force (which, after all, proves nothing), than these congresses, where the strife is between men of science, their object being to vie with each other in devising means for the relief of human suffering."

Mr. Erichsen has by this time reached America, on a social visit of a few months. He said to me that he anticipates great pleasure in meeting some of his surgical friends in Philadelphia, and I think that we will have the honor of seeing him there early in October. The medical profession in the United States will regret the unfortunate failure of Sir Henry Thompson to continue his journey. He was obliged to return, leaving the steamship at Queenstown, on account of the illness of his daughter. We may yet expect a visit from him, but he says, with expressions of great disappointment, that it cannot be during this season.

I think that now, after much professional intercourse abroad, and when near the end of my European tour, I may deduce as a corollary that, although England and America may differ much in governmental and social characteristics, and are separated by a vast ocean, the medical profession in both countries is indissolubly united in one common bond that has for its object the blending of science with humanity.

Truly yours,

R. J. LEVIS.

VIENNA, August 14, 1874.

TO THE EDITOR OF THE PHILADELPHIA MEDICAL TIMES:

DEAR SIR,—As my first letter, I will try to give you a description of the public hospitals of this city, which I think will be of interest to your readers.

The Vienna K. K. Public Hospital was opened as such by Emperor Joseph II., on Monday, August 16, 1784, ninety years ago. It had formerly served for a poor-house, founded by Emperor Leopold I. in 1693, and finished as late as 1769. In 1832 another building was added to those finished in 1769, which was completed in 1834, under the government of Emperor Francis I.; and in May, 1862, the large and fine building for pathologico-anatomical purposes was opened.

The hospital serves for the purposes of treating the sick and for instruction in the different branches of medicine. During the summer term of 1873 there lectured here twenty professors, twenty-three privat-docenten, and sixteen assistants.

The institution has thirteen large yards, which are converted into fine gardens, planted with trees, flowers,

and bushes, and provided with fountains, and has an area of 26,718 square feet, of which the different buildings take up 6350 square feet and the yards and gardens 20,368 square feet. Since the city has been enlarged, the hospital is situated near the heart of the city, which has a population of about 800,000 inhabitants. The gardens supply the patients with plenty of pure and fresh air.

The hospital contains one hundred wards for the treatment of the sick, with two thousand beds, which are distributed as follows, viz.:

For internal (medical) cases, 407 men and 280 women	687 beds.
" external (chirurgical) cases, 314 men and 205 women	519 "
" diseases of the eyes, 85 men and 76 women	161 "
" diseases of the ears, 11 men and 8 women	19 "
" venereal diseases, 222 men and 99 women	321 "
" cutaneous diseases, 89 men and 49 women	138 "
" reserve for variolous cases, 14 men and 12 women	26 "
" reserve for cholera cases, 10 men and 8 women	18 "
" psychiatric cases, 39 men and 21 women	60 "
" paying patients, 17 men and 14 women	31 "
" students, 20 men	20 "
Total, 1228 men and 772 women	2000 "

Besides those annually treated in the different wards, medical advice is given in this institution free of charge to those who do not need to stay in a hospital. Those who are received in the different wards have to pay twenty-five guldens per month. Those who want better accommodations have to pay two guldens and upwards per day, for which purpose thirty-one beds are set aside. Persons of both sexes upwards of the age of five are taken care of here. Infants and children up to the fourth year, inclusive, are taken care of in the St. Ann Hospital for Children, under the direction of K. K. Public Hospital, which has also the direction of the two other public hospitals, the K. K. Bezirks-Krankenhaus Wieden, with six hundred beds, and the Rudolph Stiftung, with eight hundred and sixty beds.

There are two chapels connected with the institution: one is used for daily service, the other, for paying the last tribute to the deceased.

The bath-houses connected with the institution are twenty-three feet long and four feet wide. The first and largest bath-house contains, besides two bath-tubs,—each of which can be filled with fourteen buckets,—the water-bed of Prof. Hebra. This is constructed of sheet iron, lined inside with zinc, and contains nearly sixteen buckets. An iron frame, with straps spread

across, over which is laid a woollen blanket, constitutes the base of the water-bed, and can be raised or lowered by a hinge. The bed is also so arranged that the patient who occupies it can be lowered or raised with it as required. Either cold or warm water is furnished, and the temperature can be regulated at any time.

The bath-tubs are made of copper, or sheet-iron, lined inside with zinc, and painted outside with oil-colors.

The bathing institution is under the direction of a bath-inspector.

In 1871, 42,854 simple baths, 2212 steam, and 2670 douche-baths were administered, besides 20,061 buckets of warm and 22,365 buckets of cold water given to 5015 patients in the different wards, for which purpose the wards are furnished with transportable bath-tubs.

The cleaning and washing of the bed-clothes and clothes of the deceased is done outside of the hospital, by a contractor. At present the daily dirty wash consists of 7500 pieces. The contractor has to take charge of the dirty wash at the hospital, and to return the clothes in five days.

P.

(To be continued.)

PROCEEDINGS OF SOCIETIES.

BIOLOGICAL AND MICROSCOPICAL SECTION OF THE ACADEMY OF NATURAL SCIENCES.

SEPTEMBER 7, 1874.

DIRECTOR W. S. W. RUSCHENBERGER, M.D., in the chair.

DR. J. GIBBONS HUNT asked permission to read portions of a letter from Mr. Charles Stodder, a corresponding member of the Academy, in reference to blood-stains.

Mr. Stodder writes, "There have been in this State—Massachusetts—two criminal trials in which the possibility of determining microscopically between human and horse's blood was important. In both cases, 'experts' were diametrically opposed to each other as to the possibility of recognizing any difference. It seems to me that it is not creditable to the science of microscopy of the present day that there should be such a difference of opinion.

"I think Dr. Richardson is right in advocating the use of high powers in making observations in such cases. My idea of a high power now is nothing under a $\frac{1}{2}$ (1200° with low eye-piece, or 4800° with $\frac{1}{4}$ -inch eye-piece), and from that up to a $\frac{3}{8}$; and I cannot consider your objection to Dr. R.'s theory sound, viz., 'that serious loss of definition generally went hand in hand with gain in amplification.' This may be your experience, as it has been that of almost every one who has purchased a $\frac{2}{5}$ or $\frac{3}{8}$ made abroad, but the performance of Powell & Leland's $\frac{1}{8}$ and Tolles's $\frac{1}{8}$ in the hands of Dr. Woodward, and of Tolles's $\frac{3}{8}$ in the hands of Mr. Moorehouse and of G. B. Harriman, of Boston, results that have been published and are before the public, should have dissipated such belief.

"Now, it is by the use of such instruments that will give good definition with a magnification of 2000° to 20,000°, that histology has hereafter to be studied, but it will take twenty years for the doctrine to be generally accepted; and such instruments and powers must be

used for the measurement of the *differences* in size between the various blood-globules, and such I take it to be what Dr. R. means."

"Now, Mr. Director," proceeded Dr. HUNT, "I will ask permission to make some remarks in reference to this interesting letter, and also on the subject of high-power definition, from my point of view. With Dr. R. and Mr. Stodder I quite agree in a common want for high amplification, but, in connection with high amplification, I want especially sharp definition and freedom from color; and I must still be allowed to say that all my trials with such high-power lenses as a $\frac{2}{5}$ and $\frac{3}{8}$ have only confirmed my previous disappointment.

"Reference is made in the letter to the performance of high-power lenses in the hands of expert microscopists. But I will ask you to observe this fact, viz., that all such reported trials are tests by oblique illumination. Now, under such conditions, it is not possible to judge of the best corrections of a lens for either chromatic or spherical aberrations; neither do opticians *correct* their objectives by such illumination. Therefore I do not attach much importance to such published trials, as full reports of *all* the qualities of such lenses, but only of *special* points which they may possess.

"If my $\frac{3}{8}$ resolves the Amphipleura clearly into lines or dots according to the special illumination, and I simply state the fact, microscopists can judge quite correctly of its power in that direction, because on the test diatoms are structures of known size or distances apart, and marvellously alike on the average: hence from these diatoms we have derived a language understood by all, by which we can communicate the performance of lenses in such work. But turn this same $\frac{3}{8}$, which resolves the lines so readily, on a bacterium, or salivary corpuscle, or yeast-globule, or white blood-corpuscle, and adjust for central light for best definition, and we have no language as in the case of diatoms by which to express the 'unhappy luminosity' which surrounds such ordinary objects of histological observation when viewed under the $\frac{1}{2}$ or $\frac{3}{8}$ objective. In other words, these high-power lenses which resolve the diatoms by oblique light—and it may be done without difficulty by lenses of much lower power—fail to define sharply and free from color such objects as I have mentioned, by central light.

"Let me illustrate my meaning by analogy. We know that it is customary to grade applicants for admission into college classes in proportion to their proficiency in mathematics. Now, physiologists acknowledge that special brain-development endows the mathematician. A boy may have that special organization and be an accomplished mathematician, but be quite backward in all other departments, or he may not possess this special brain-development, yet be an accomplished scholar in literature and many branches of science; still, he is graded obliquely by his mathematics. Does such testing convey any just idea of the boy's intellectual acquirements? For the teacher such testing is convenient, but for the boy it is *unjust*, and gives no indication of his general mental aperture. It is just so with our judgments in reference to high-power lenses. Like acrobats, these instruments will perform some difficult feats, but when employed on objects of ordinary histological research by central light, my experience teaches me they are not yet corrected for satisfactory definition.

"The so-called podura scale would be a good test for perhaps *all* the qualities of such lenses, and, like the diatoms, is known to all microscopists; but it is impossible to obtain slides with covers thin enough to be used.

"Two things are essential in all real microscopical work, and one is as important as the other. These are a good lens at one end of the tube, and a good brain at the other; and wide differences in definition and aperture exist in both.

"After all, microscopical work is only another way of seeing. It requires natural qualification and special training, in which all are not competent. One individual may listen to the music of the sublimest orchestra and hear only the general melody and derive only a sensation of general pleasure; another will follow tenaciously each separate instrument, and yet combine the whole into one sweet harmony immeasurably beyond the conception of the other. It is so with gazers down the tubes of microscopes. Most people derive a gratifying sense of general pleasure; a few see many visible things, as definition, quality of field, character of illumination, color, etc., properties of the lens; also form, color, size, and structure, properties of the object; and all at one view. It will always be so."

Dr. J. G. RICHARDSON replied in answer to these remarks that, plausible as were the arguments and striking the analogies brought forward, he believed that the truth or falsehood of the proposition that "serious loss of definition (in the use of high powers such as the $\frac{1}{25}$ and $\frac{1}{30}$) generally went hand in hand with gain in amplification," was chiefly to be established by an unbiassed examination of the downright facts. In the case under discussion, it was admitted that, for fifty years past, blood-stains had been investigated by some of the ablest microscopists of Europe and America, for the express purpose of discriminating the kinds of blood by the appearance of the corpuscles, yet without success; and it was also admitted that he had (see *Philadelphia Medical Times*, July 18, 1874, p. 665), in six different dried stains, distinguished the kind of blood with perfect correctness, by microscopical examination. Under these circumstances it appeared as if there was no escape from the conclusion either that he (Dr. R.) was a more skilful microscopist than the great masters of the art above referred to, or that he had made the discoveries described by the aid of superior lenses—"improved tools"—over those which had previously been employed; and therefore, being persuaded that his friend Dr. Hunt was too inexorably unprejudiced in his favor to acknowledge the former preposterous alternative, that gentleman seemed to be necessarily impaled upon the other horn of the dilemma, and must, perforce, admit that, in the examination of blood-stains at least, the advantages of "gain in amplification" exceeded the disadvantages entailed by "loss of definition," in the use of high powers such as the $\frac{1}{25}$ and $\frac{1}{30}$ objectives.

As a further and even more direct evidence that superior lenses were the source of these and other discoveries, he might mention that, previous to the purchase of a $\frac{1}{25}$ from Mr. Wales, six years since, he had hundreds of times tested his $\frac{1}{4}$ -inch objective, by endeavoring to obtain with it and the A eye-piece a view of the moving molecules in the salivary corpuscles, but uniformly without success. Yet on the second trial of the $\frac{1}{25}$ lens, and on the very first in which he obtained a suitable illumination, he saw at once and with beautiful distinctness this curious movement of the granules, for which he had so many years been vainly searching with inferior tools.

Dr. RICHARDSON added that, in reference to the process of measuring the fresh or dried blood-corpuscles of different animals, there was one important but purely mechanical advantage attending the employment of high powers, to which he wished to call the attention of members. When measuring the diameter of the various disks by means of the cobweb micrometer, the operation, as is well known, is analogous to that of finding the size of a number of small circles upon paper with a pair of blunt-pointed dividers; and since the micrometer-threads in the one case and the compass-points in the other remain always the same size, it is easy to see that errors in manipulation, arising from the difficulty of deciding when the threads or points *exactly*

coincide with the margins of the objects to be measured, will be much less important if those objects vary from $\frac{1}{8}$ to $\frac{1}{16}$ of an inch (as the blood-corpuscles spoken of appear to do under a $\frac{1}{30}$ lens), than if their diameters only range from $\frac{1}{25}$ to $\frac{1}{16}$ of an inch, which are about the limits of their apparent magnitudes as seen beneath a $\frac{1}{4}$ -inch objective.

REVIEWS AND BOOK NOTICES.

COCAIN, VERATRIA, AND GELSEMIUM: TOXICOLOGICAL STUDIES. By I. OTT. Philadelphia, Lindsay & Blakiston, 1874.

The United States has produced, thus far, so little good, original work in physiology, that every new production of the sort is doubly welcome: welcome as new scientific truths always are, and welcome also as the offspring of the new and higher ambition which is permeating the profession in this country. The little brochure before us contains much thoughtful, careful, good work, and certainly demonstrates not merely the close acquaintance of the author with the ways and instruments of modern physiology, but shows that he possesses the ability to use this knowledge in the acquisition of new truths. Surely the harvest is ready, but the reapers are few. Let us hope that this new worker shall have the continuous activity, as he has the ability, to win a recognized place among the world's physiologists.

THE MEDICAL REGISTER AND DIRECTORY OF THE UNITED STATES. By SAMUEL W. BUTLER. Philadelphia, 1874.

This volume, of about eight hundred and fifty pages, is the crowning work of a very busy and useful life, and is a legacy of no mean value to the profession. The immense labor necessitated in its compilation may be known by the fact that within its pages are embraced the names, addresses, and educational and professional status of over fifty thousand physicians, with lists of medical societies, abstracts of laws affecting the profession, and a great amount of other miscellaneous matter. The editor, some fifteen years ago, commenced collecting the names of physicians, and in course of time obtained some twenty thousand; but in 1871 he purchased from Dr. Toner, of Washington, D.C., a list of about forty-eight thousand physicians, of all schools and classes, obtained from the internal revenue department. To each of the addresses in this list a circular, asking for information, has been sent by Dr. Butler, and upon the replies to these, and the information derived from alumni lists, transactions of medical societies, and other allied sources, the present volume rests. No doubt there are some mistakes and numerous omissions in it, but, in the language of the preface, "those only who have neglected to reply to the circulars are responsible for them." To publishers, druggists, and those members of the profession whose sympathies and needs are wide enough to reach beyond their own immediate neighborhood, this book must be invaluable. We trust that the pecuniary result will be such that the family of the editor will reap a rich harvest of substantial reward: certainly the reputation of Dr. Butler will for many years be kept alive as that of the man who dared and successfully achieved the herculean task of cataloguing the American profession.

A PRACTICAL TREATISE ON THE DISEASES OF WOMEN. By J. GAILLARD THOMAS, M.D. Fourth Edition, revised. Henry C. Lea, Philadelphia, 1874.

As a new edition of this book appears about once a year, we do not feel called upon to do more than chronicle the successful termination of the fourth labor of its author.

SELECTIONS.

REUMONT ON METALLIC POISONING AND ITS TREATMENT BY MINERAL WATERS.

THERE are two kinds of quicksilver-disease; that of artisans, which is produced in the practice of various arts in which mercury is employed; and medicinal mercurialism, which is produced by mercury introduced into the system for medicinal ends. Both sorts are in their nature very similar, and differ chiefly in the degree of acuteness of their symptoms, and according to the presence or absence of combinations with affections of the system previously existing,—especially syphilis.

Of the alteration produced in the blood by mercury we know little, and that little is contradictory. Overbeck's careful researches lead him to believe that mercurialism produces a sort of anæmia, that in mercurial blood the quantity of blood-corpuscles and of albumen is diminished, while its coagulability is increased, and its amount of water is fluctuating. It seems to be established that all preparations of mercury, if introduced into the system in sufficient quantity, induce an increased excretion of bile, and sometimes a passage of albumen through the urine.

As to the form in which mercury quits the system, little is known with accuracy. In the alimentary canal it is found as sulphuret of mercury. It is not determined in what shape it appears in the perspiration. As to the stories of metallic mercury being given out in baths, they require no serious consideration; although it is certain that gold and silver articles worn by those who are taking mercury occasionally become stained by an amalgam. It has been concluded that mercury in the urine is in the shape of an albuminate, chiefly because the urine of patients under mercury often contains albumen. On the whole, the view of Overbeck is probable, that mercury is not eliminated from the system until it has been separated from its albumen.

The question how long mercury remains in the system is one of practical importance. The anti-mercurialists speak, in support of their favorite views, of its remaining many years in it; but there is no proof of this. According to Overbeck and Waller, the spontaneous elimination of mercury proceeds slowly, and may occupy seven months, or even longer. Kussmaul speaks of many months, up to twelve, and even more. The organs which appear to retain the mercury the longest are the liver and the kidneys, and the liver contains most.

Kussmaul and Overbeck have done the great service, by their researches, of dispelling in a great measure the mistaken views which have prevailed among physicians respecting the relation of syphilis to mercury. "A twofold picture of mercurialism," says Kussmaul, "runs through our literature; one painted by those who have studied it as it occurs among quicksilver-workmen, the other by those who study syphilis. The first picture has altered little in the course of time; the second has always varied according to the course of opinions on syphilis. A set of fanatical anti-mercurialists put down every ailment in the whole course of the life of a man, who may have once taken a few grains of mercury for syphilis, to the account of the metal; and looked on syphilis as a very mild disease, unless aggravated by the use of mercury. The most violent even denied that there was such a thing as syphilis, regarding it only as mercurialism."

In its best-marked and really frightful form, true mercurial disease is rarely witnessed except in quicksilver-workmen; it shows itself in a much milder form in those who have used mercury only for medicinal

purposes. In the mercurialism of artisans there are three stages of development,—the stage of erethism, that of tremor, and the final stage,—although there is no marked line of distinction between them. In all stages, the nervous system is affected in a marked degree. Such marked stages are seldom or never to be seen in mercurialism from the administration of the metal, and the symptoms are seldom simple; they are almost always combined with those of syphilis or of some other disease.

The pure symptoms of mercurialism occurring after the medicinal use of the metal that occur most frequently are either general or local: anæmic and chlorotic conditions; disturbance of nutrition, showing itself chiefly in emaciation and in muscular weakness; gastric and febrile conditions; affections of the nervous system, such as painful sensations, gnawing rheumatic pains, tremors, and paralysis; and, consequent on these, swimming in the head, loss of memory, etc. But these last symptoms undoubtedly belong more or less to syphilis also. The commonest local symptoms are shown in the mucous membrane of the mouth, the tonsils, the salivary glands, and, in fresher cases, in the mercurial rashes.

In both mercurial and syphilitic affections there is a certain alteration in the blood; but it must vary in the two, as the symptoms to which it gives rise are very different. In syphilis, one of the first symptoms is the swelling of many of the lymphatic glands, whereas we have only rarely in mercurialism some swelling of the cervical glands, as a consequence of stomatitis. The pathological productions of the two diseases are very different. The mercurial dyscrasy must be viewed, on the whole, as a catalytic process, which has little to do with new or plastic formations, and which, at most, causes some thickening of the mucous membranes and the enlargement of a few glands; while syphilis shows the greatest tendency to hyperplastic and new formations. Soft nodes (gummy exudations) occur in syphilis only.

As regards the further question whether mercurialism does not impart a malignant character to syphilis, we may reply that the worst forms of syphilis occur in those who are not treated at all, or certainly not with mercurials; while we grant that the solvent action of mercury may be prejudicial in phagedænic and sloughing ulcerations. As to the affections of the bones ascribed to mercurialism, we have already said that only local ones of the jaws, connected with profuse salivation, are ever produced.

If lead be introduced into the system for any length of time, in small quantities, the characteristic symptoms of lead-poisoning are produced. Lead is partly inhaled in extremely minute particles, partly taken up in the intestinal canal, partly introduced through the skin, or through the nasal passages in snuffing into the circulation. It is probable that all preparations of lead become converted in the intestinal canal into albuminates, which, being dissolved in the stomach, are partly introduced into the system. It is not known in what form it exists in the blood, but it occurs in it in smaller quantities than in other parts of the system. From the blood, the lead passes into the parenchyma of various organs.

Little is known of the mode of operation of lead in the system, though it has been generally believed that it has a special affinity for the voluntary muscles, and occasions paralysis of them and loss of their electro-muscular contractility. But Heubel has recently arrived at some important conclusions. He finds that the relatively greater quantity of lead accumulates first in the osseous substance, and next in the kidneys. After this come the liver, the central portion of the nervous system, and only after these the muscular and

intestinal fibres. Heubel, therefore, rejects the theory that blood impregnated with lead has a power of contracting the muscular coats of arteries and of veins. Heubel, regarding the liver and kidneys as being merely the organs that eliminate lead, and on that account contain a large portion of it, thinks that lead has, on the whole, the greatest affinity to the nerve-substance.

The elimination of lead from the system, apart from what passes through the intestinal canal as sulphuret, takes place most frequently through the biliary secretion. It has been assumed that lead is eliminated through the skin, owing to the dark color of the skin after sulphur-baths which has occasionally been observed. The occurrence is undoubtedly very rare, and is explained by the action of the sulphur of the water on particles of lead lying in the folds of the skin.

Lead-poisoning has of late years become more frequent, owing to the use of cosmetics and of snuff containing the metal. It sometimes requires much discrimination on the part of the physician to discover it. The blue line on the gums is often a most valuable sign. The peculiar symptoms of saturnism are, according to their frequency, lead-colic, pains of the joints, paralysis, affections of the brain, anæsthesia. The characteristic paralysis attacks most frequently the fingers, the hands, and the fore-arms; less often, the lower extremities. The great characteristic is the loss of extensor, not of flexor, power.

As to other metallic poisonings, chronic arsenical poisoning is rare. Some doubt whether there is such a thing as chronic copper-poisoning, but paralysis of the extremities is said to characterize it.

It would be very desirable to explain how sulphur-waters are able to fulfil the indication of disengaging the metal stagnating in the system, and of causing its quicker elimination through the skin, liver, and kidneys. To account for it, Astrie has propounded the theory with reference to mercury and to lead, that the sulphurets of the alkalies and the sulphate salts render the metallic albuminates soluble, and that the albuminates, having been made soluble, are conveyed out by means of the secreting organs, whose functions have been heightened by the whole process of a water-cure. Probably the sulphur-waters act in this case by dissolving the protein compounds. For the present we must be satisfied to use such chemical views as working hypotheses, and indeed they are supported to a considerable extent by clinical observation, although there is no doubt that there are other factors concerned in the elimination of metals.

We know as yet few facts which prove direct elimination of metals by the use of sulphur-waters. The occasional occurrence of mercurial stomatitis and salivation during a sulphur-water cure in patients who have used mercury even at a considerable distance of time, can only be explained by the blood's taking up metal which had been combined with the tissue of organs. There are analogous cases of the reappearance of symptoms of lead-poisoning in patients who had been apparently cured of it. Although we can receive only with the greatest reserve old and new stories of metallic quicksilver being found in the baths used by mercurialized patients, or in their cutaneous eruptions during a bath-cure, yet it would seem that the metal is sometimes eliminated through the skin. Besides the case quoted by Overbeck, two cases have occurred to me (Reumont) and to my colleague Diemer, which can scarcely be interpreted in any other way than as instances of elimination of mercury in the form of sulphuret in the perspiration. I have in strongly mercurialized patients observed, by the electrolytic process during the cure at Aix, mercury in very minute quantities in the urine. Hemmann, of Schinznach, has made the

statement that he has washed metallic mercury from the fæces.

Like mercury, all other metals must, under treatment which relieves the symptoms, be extracted from the tissues. And when Tanquerel speaks of a black appearance of the skin in cases of lead-poisoning treated with sulphur-baths, he attributes this, as has been already remarked, to the union of sulphur with minute portions of mercury in the folds of the skin. I have (says Reumont) several times observed somewhat similar effects in those treated with mercurial inunction and sulphur-baths.

But much more important for the physician than the theory of their operation is the clinical observation of the value of sulphur-waters in metallic poisonings. The mercurialism of artisans naturally is seldom sent for treatment to baths, whereas medicinal mercurialism is very common, and very frequently complicated with syphilis. Some of the most renowned practitioners bear testimony to the value of sulphur-waters in such cases. Robbi commences his cure with sulphur-baths, Himby recommends them in mercurial amaurosis, Horn and Romberg in tremor, Roth in mercurial hoarseness. Many French, Swiss, and German physicians, besides those of Aix-la-Chapelle, are equally loud in their praise.

As to the method of using sulphur-waters in such cases, it is necessary to introduce the sulphur into the blood in every variety of way. Baths, drinking, and inhalations all come into play, and douches or vapor-baths are of special use in helping the elimination of the metallic molecules.

Chronic lead-poisoning has of late years been pretty frequently treated at sulphur-baths; it has generally been caused by food or drink containing lead, by cosmetics, or by snuff. Men of great clinical repute, as Schönlein, Romberg, Autenrieth, and many others, have had the greatest faith in its treatment by sulphur-waters. I myself have cured by them various cases of paralysis and colic induced by snuff.

There are very few notices of the treatment of arsenical or copper-poisoning by sulphur-waters. But there are a few successful cases on record. I myself treated with success a case of arsenical poisoning brought on by stuffing animals with arsenical paste.—*London Medical Record*.

THE WHARTON CASE.

DR. EDWARD WARREN writes to the *Baltimore Bulletin* of Saturday, August 29, enclosing two letters, which we give in full below. The cause of the correspondence was the passage, by one of the Baltimore medical societies, of a resolution which said in substance that the decision given by Prof. Taylor in his work on medical jurisprudence was of no import, because it was formed on biased and incorrect evidence as to the facts sent him by an "expert for the defence." Dr. Warren is the expert for the defence alluded to:

"15 ST. JAMES'S TERRACE, REGENT PARK, }
"June 27, 1874. }

"Dr. Warren Bey, Cairo :

"Dear Sir,—Your letter dated Cairo, June 13, has been forwarded to me by Dr. Stevenson. In answer to your interrogatories, I beg leave to say,—

"1. That I received a copy of the *Baltimore Gazette's* report of the Wharton-Ketchum trial. It was addressed, not to me personally, but to the Professor of Chemistry, Guy's Hospital. As I had resigned the office, the report fell into the hands of my successor, Dr. Stevenson, and he had it in his possession for some weeks, when he handed it to me, as being originally intended for me.

"2. You did *not* furnish me with any other statement, report, or documents relating to that trial or any other subject.

"3. You did *not*, by any word, hint, or act, comment on the evidence given at that trial, or in any way attempt to influence or bias my judgment in regard to it.

"4. The premises for my decision regarding the case of General Ketchum were derived chiefly from the report of the *Baltimore Gazette* (sent by you, as I now find).

"Taken as a whole, *I do not consider that the symptoms have any resemblance to those which are observed in poisoning with antimony*, and a further examination of the case has satisfied me that this is the only conclusion to which the *medical* facts lead. In the Guy's Hospital report for 1857, I collected and reported thirty-seven cases of poisoning with antimony. Upon the facts here collected, and others which have come to my knowledge since, I believe that the death of Gen. Ketchum was *not caused by antimonial poisoning*.

"The chemical evidence did not conclusively show the presence of antimony in the articles submitted to analysis for evidence at the trial. There was a fatal omission in those who attended on the deceased in his last illness. The *urine* was not examined for antimony while the patient was living. The only conclusion to be drawn from this omission is that those who were in attendance on the general did not suspect that his was a case of antimonial poisoning while he was living and undergoing medical treatment, or they wilfully neglected to adopt the best mode of verifying their suspicions and counteracting the effects of poison.

"As, before this occasion, I have never received any letter from you or corresponded with you in any way, I must express my surprise that it should have been imputed to you that you have in any way attempted to influence my judgment. I did not even know that you had sent me the report of the *Baltimore Gazette* until Dr. Stevenson informed me, long after its arrival in England. You have my authority for stating as publicly as you please that such an imputation is utterly untrue, and, if made by a professional man, most unjustifiable. My opinion of the Ketchum case was formed apart from all local influences and prejudices. Having now had an experience of *forty-three years* in the subjects of poisoning, and an opportunity of examining, during that period, some hundreds of cases, I feel myself in a position to act independently of all hints or suggestions. To extra-forensic statements in a case like this I give no attention.

"I presume the telegram which you quote in your letter refers to me. You are at liberty to state in reply that no experts for prosecution or defence made any application to me in reference to this trial, or furnished me with any premises or information respecting it. The whole story is a falsehood from beginning to end. I see that Dr. Reese has been implicated in the matter. I do not know him, except by name. I never wrote to him or received any letter from him respecting this trial. I am,

"Yours, very truly,
"ALFRED S. TAYLOR."

"21 CAVERSHAM ROAD, }
"LONDON, N. W., July 3, 1874. }

"To His Excellency Warren Bey, Cairo, Egypt:

"My Dear Sir,—I forwarded your letter to my colleague, Dr. Alfred Swaine Taylor, F.R.S., and he has handed me the letter which I now forward to you. I have read it at his request, and I can speak with *knowledge* as to the circumstances under which he became acquainted with the Wharton-Ketchum case. In May, 1872, I received by post, at Guy's Hospital, a pamphlet,

being a reprint from the *Baltimore Gazette*, of the report of the trial. I had no knowledge of the case before, and was ignorant in regard to the sending of the report until I came to your evidence, when I found your name interlined, and *with the simple word 'Compliments,' added in pencil*. When I had read the report I handed it to my predecessor in the chemical chair, Dr. Taylor.

"My own opinion of the case, from reading the report, was this: that *the chemical evidence broke down and did not prove that 'twenty grains of tart. emetic were administered to Gen. Ketchum,' and that the symptoms were not characteristic of antimonial poisoning and might have been produced by natural causes*, etc., etc. Both Dr. Taylor and I think that you may fairly disregard all attacks on your character, as every one is liable to them. As for furnishing 'false data,' I know that all you furnished was *The Gazette's* report.

"Very truly yours, etc.,

"THOS. STEVENSON,

"Professor of Chemistry, Guy's Hospital, London."

GLEANINGS FROM OUR EXCHANGES.

TOMMASI ON THE USE OF CARBOLIC ACID IN CHEESY PNEUMONIA.—Professor Tommasi states (*Il Morgagni*, January, 1874, quoted in *Gazzetta della Clinica*, May 19) that he has found carbolie acid very useful in cases of cheesy pneumonia which have gone on to the formation of pulmonary abscess. The medicine is administered in the form of solution (one part in forty of water, sweetened). In two years he has met with six cases, of which he relates two.

The first case was that of a boy, aged six, who had hectic, sweats, extreme emaciation, and moderate expectoration of sanguineous fetid pus. Cinchona, lactate of iron, cod-liver oil, and raw meat produced but little improvement. He now had half a gramme of the carbolie acid solution daily, the dose being increased to a gramme. At the end of a fortnight the fever ceased, the expectoration diminished and became inodorous, and in four months he was quite restored to health.

In the second case, there was abundant expectoration of inodorous pus. The usual restorative means failed; but, after the solution of carbolie acid had been given in daily doses of a gramme to a gramme and a half, the expectoration diminished, and the patient became free from hectic and regained his appetite, and his nutrition was improved. In two months the expectoration had ceased, and a respiratory murmur, though weak, could be heard in the portion of lung which had been hepatized.—*A. Henry, M.D.*, in *London Med. Record*.

APPLICATION OF AUTOPLASTY BY THE FLAP METHOD FOR THE CURE OF SALIVARY FISTULA (*The Medical Press and Circular*, August 26, 1874).—Mr. J. Morgan has found the flap autoplasic method the most successful in the treatment of salivary fistula. He illustrates his plan of procedure by the following case:

A child three years of age had suffered from abscess of cheek, followed by fistula of the parotid, just as the duct emerges from it. The opening was about the size of a very large pin-hole, with puckered edges; the quantity of secretion poured out at times was incredible, and saturated the child's clothes, giving constant annoyance. The patient had become irritable and pallid, and suffering evidently from imperfect nutrition.

For some time he tried with perseverance the application of collodion, pressure, caustics, paring the edges

and coapting them, but with imperfect results. He finally adopted the treatment by flap. A flap of skin was raised up from immediately above the fistula, the parts below and in its vicinity being also denuded. He then drew down the flap over the fistula, and attached it by points of fine suture, and coated the whole over with flexible collodion, which was renewed from day to day when required. The result was most satisfactory. After eight days the collodion was discontinued, and a perfect cure was effected. The child's condition improved incredibly in a very few weeks.

HYPODERMIC INJECTIONS OF BLOOD (*Medical Record*, September 1, 1874).—Considering the difficulties and dangers which are the obvious objections to the operation of transfusion of blood as ordinarily practised, it has occurred to Dr. Landenberger, of Stuttgart, that in many cases a fair substitute for it may be found in hypodermic injection. In one case where he has tried it the result was favorable. It was the case of a patient who was in a condition of collapse following long-continued vomiting, due to some form of obstruction of the bowels. Defibrinated calves' blood was used, and, although only eight grammes were injected, the effect was an almost immediate improvement. The patient revived, the temperature rose one degree, the pulse became again perceptible, vomiting ceased, and a certain amount of nutriment could be again retained in the stomach. This improvement lasted forty-eight hours, but was afterwards followed by collapse again. The only cases in which absorption of the injected blood will not take place are those in which the circulation is utterly depressed, as in the asphyxia of cholera, or the very last stages of phthisis, when the injection causes simply a suggillation.—*Med. Corr.-Blatt*, 20, 1874.

A SMALL ANEURISM ON THE DORSUM OF THE TONGUE (*The Lancet*, August 22, 1874).—Mr. John Gay reports the case of a lady, æt. 45, who had a pulsating tumor about a third of an inch from the tip of the tongue, and slightly to the side of the mesial line, about the size of an ordinary pea. The surface of the tongue was desquamated for some little distance around it, and the free wall of the tumor (which rose slightly above the general level) was obviously very thin. No doubt could be entertained of its being an aneurism, fed by a small artery, which could be very distinctly felt below the surface of the tongue for the space of half an inch approaching it from behind. Pressure on the artery arrested the pulsation in the tumor and emptied it. It had existed or been noticed for a period of six months. It was clearly an aneurism on an abnormally developed branch of the ranine artery. It was readily extirpated by a few strokes of the knife, and the resulting hemorrhage was easily controlled by passing one of the sutures through the supplying artery.

MISCELLANY.

PRACTICAL CREMATION.—Madame Fortmeyer, a midwife, was recently arrested in St. Louis for committing an abortion. At the investigation it was proved that Madame Fortmeyer had a unique and original method of ridding herself of all tell-tale evidence. A favorite aphorism with her was, "*Ashes tell no tales.*"

This very pleasant and amiable person indulged in the pastime of *burning* the results of conception; and it was shown at the inquest that she had *roasted* in her stove the bodies of living, breathing infants.

"Surely," says the *Missouri Clinical Record*, "this intelligent lady should be rewarded for inaugurating in this country a practical demonstration of incrimination; but we are afraid—notwithstanding the efforts of humane lawyers in her behalf—that she will be rewarded quite otherwise."

MEDICAL CHARITIES IN ST. LOUIS.—There are thousands and tens of thousands of people in our large cities who, if they can get medical attendance and medicines gratuitously when sick, and quarters in hospital if disabled by accident or disease, will never provide for a day ahead, but spend half their earnings at dram-shops (for the number of which St. Louis has an unenviable reputation). The more charity, the more left for whisky; and the more whisky, the more charity needed; until the city is given over to saloons and charity-institutions: one-half of the population engaged in making drunkards, and the other half working hard to take care of them.—*St. Louis Medical Journal*.

UNIVERSITY OF VIENNA.—The total number of matriculated students in the University of Vienna during the year 1873-4 was 7526; of whom 1109 were medical students in the winter session, and 1036 in the summer session. The number of new entries in the medical department was 194. Among the largest medical classes were those of Professors Brücke (885); Hyrtl (680); Bamberger (540); Billroth (509); Dumreicher (495); Rokitsansky (354).

DR. EDWARD WARREN, whose rapid advancement in Egypt we have already chronicled, has very recently been promoted to the position of Surgeon-General of the Egyptian Army,—the highest medical office in the gift of the government.

DR. BUCHANAN, of bogus-diploma notoriety, was arrested, Wednesday, September 16, whilst on his way to the Eclectic College, on the charge of having caused the death of a Mrs. Isaac W. Vandegrift by an improper surgical operation.

NOTES AND QUERIES.

THE MILITARY EXPRESSION OF MEDICAL RANK.

TO THE EDITOR OF THE PHILADELPHIA MEDICAL TIMES:

SIR,—I, for one, entirely concur in the views of "Rank," expressed in your issue of August 29, as to the military position of army medical officers. There is no logical reason why, at least in military circles, we should not be addressed by military titles; and frequently positive advantage would accrue. It's all very well to say,

"Rank is but the guinea's stamp,
A man's a man for a' that,"

but the fact that the guinea is stamped is what gives it currency and practical if not intrinsic value, and this is particularly true in the army at large.

It makes one a no better physician to be addressed as captain or colonel, but it tends, insensibly perhaps, to increase the respect of those officers and men who are taught to measure authority by position. It assists, in other words, in the assimilation into the military body; and a man who does not have the military spirit should not be in the service. Any one who feels himself an "outsider" should make an appreciable vacancy, and not remain as a round peg trying to fill a square hole. A medical officer is more than a mere doler-out of pills and powders. His highest functions are in the preventive, not curative, care of men, and he cannot exercise them without he has a lively interest in the service as such.

I think that it will be recognized by those familiar with the *personnel* of the corps, that, as a rule, the more military a medical officer is the more efficient he is. Martial tastes do not supply professional knowledge, but they develop those particular features of it that enable one to discharge well his commission. The man who shelters himself behind the petticoats of non-combatism, and who shirks his share of the general (not special) duties of garrison, is apt to be the one who, however wisely he may prescribe for the bedridden, is most frequently imposed upon by malingerers and is unfortunate in the management of his department.

Surgeon and assistant-surgeon are admitted misnomers as they are applied. If the committee that is to represent the interests of the corps before Congress this winter can get the organic law so changed that our commissions will be those of first-lieutenant, captain, and major in the medical department, a positive and practical advance will be made. For even if they fail to get the colonelcies sought, those grades will necessarily follow. There will be no reason for stopping promotion in the medical department with the majors, when the quartermasters and engineers (begging pardon of the latter for thus coupling them) are colonels. And by parity of reasoning hospital-stewards should be sergeants.

How medical directors can make assignments otherwise than at present I cannot see. If an officer's rank is to *entitle* him to a choice of posts, it will make endless confusion. My experience is that, as a rule, the directors do what is best for the good of the service with both fairness and consideration. (But then it may be that I am lucky as well as contented.)

CAPTAIN Z.

CORONERS' INQUESTS.

TO THE EDITOR OF THE PHILADELPHIA MEDICAL TIMES:

IN the number of the *Medical Times* for September 5, you declare it to be your "duty to hold up to deserved reprobation the system of loose and careless medico-legal examinations" now so prevalent in inquests by the coroner and his aids. That some one has at length had the courage or independence to call attention to the flagrant abuses of power and omissions of duty at times manifest in cases of this nature, may justly be regarded as cause of gratulation by all who desire to see an intelligent and faithful performance of what the law demands in a matter where life and property may be involved. The apathy in regard to this important subject is doubtless the result of the silence of the medical journals and the reluctance of physicians to assume, individually, a hostile attitude to an existing evil.

The remarks of the *Times* in reference to the imperfect, and, as a sequence, nearly useless examinations of the cadaver are well founded and to the point, but the subject may be presented in a somewhat different aspect. It cannot have escaped notice, at least of medical and legal gentlemen, how often the direct object in view seems to have been to force the case, either in respect to the post-mortem or the evidence taken at the moment, to assume such features as would render unnecessary any subsequent process at law. In explanation of this we do not see any other probable motive than is found in view of the loss of time, the trouble, and, perhaps, the too searching examination that might ensue, and prove anything but agreeable to those whose duty it is to discharge conscientiously an incumbent duty. Many years ago the writer was given to understand by a coroner—himself a physician—that where a case of suspicious, embarrassing character was in hand, the easiest was the best mode—that is to say, dispense, if possible, with the post-mortem. It is to be feared that the desire to receive the emoluments of office with as small an expenditure of time and labor as possible, and without incurring risk of subsequent legal process, has rather increased than diminished.

G. H.

Sept. 10, 1874.

NEWARK, N. J., Sept. 4, 1874.

A L'ÉDITEUR DU "MEDICAL TIMES":

MONSIEUR,—Dans le dernier numéro de votre excellent journal j'ai lu une discussion, extraite du *New York Medical Journal*, sur les appareils inamovibles et le plâtre de Paris, dans le traitement des fractures.

Les critiques qui y sont portées contre le plâtre de Paris ne me paraissent justifiables que par une mauvaise application, ou un mauvais procédé d'application, de cette substance. Voici comment on l'applique à l'Hôtel-Dieu de Paris.

On commence par faire la réduction, puis on recouvre le membre brisé avec une fine compresse bien huilée et faisant le moins de plis possible. On trempe dans le plâtre délayé des compresses que l'on replie ensuite de manière à en faire de véritables attelles (splints) au nombre de deux, ou trois, ou quatre, suivant le membre à entourer. Ces attelles ont toute la longueur du membre à maintenir, ou bien l'une d'elle est plus courte. On applique ces compresses quand elles sont molles et on les maintient par une bande plâtrée roulée assez serrée dans toute leur étendue. L'appareil

est sec et dur dans un temps qui varie de dix minutes à demie-heure, mais on le laisse sans y toucher jusqu'au lendemain.

Le lendemain, s'il y a à craindre la gangrène, s'il y a la plaie, s'il y a la moindre faison pour que l'on veuille surveiller le membre, le chirurgien coupe la bande plâtrée du haut jusqu'en bas et l'enlève.

Le membre reste alors soutenu par les attelles de plâtres, et on les fixe avec une bande ordinaire ou des bandelettes d'emplâtre adhésif.

L'appareil permet alors en enlevant une des attelles d'inspecter le membre sans le mouvoir, car il est fermement maintenu par les autres qui s'y adaptent dans toutes ses formes.

Ainsi utilisé, le plâtre de Paris conserve toutes ses qualités et y ajoute les avantages des appareils à gouttière ou des attelles en bois.

Voilà, M. l'Éditeur, les observations que m'a suggérée l'article indiqué. Je voulais vous les écrire en Anglais, mais vous avez des capables traducteurs que je m'évite cette peine.

Votre tout dévoué et assidu lecteur,
FRENCH PHYSICIAN.

TO THE EDITOR OF THE PHILADELPHIA MEDICAL TIMES:

DEAR DOCTOR,—Your effort in to-day's issue of the *Times* in behalf of the Homœopathic Hospital reminds me of a case which came under my charge recently, and which evidences the value of homœopaths as diagnosticians. A lady of refinement whom I was attending during confinement called my attention to her daughter, a bright child six years of age. The homœopathist (a prominent Arch-Street practitioner) who had formerly attended the family, upon being consulted as to the cause of the child's lameness, stated that "she had broken the bone of her foot, but that it would come right again." Not valuing his advice, she was referred to another practitioner on Chestnut Street, who confirmed the diagnosis, but stated that "the bone would have to be broken again, and set straight." Declining to receive the "surgeon's" advice as any more reliable than the "physician's," she told him so, and said that as the deformity arose gradually, she did not believe that any bone was broken, or that the child could receive a fracture without suffering from it at the time of its occurrence. She was informed that "they knew their business,"—which is doubtless true enough; but she put the case in my hands, and as the child was suffering from a well-marked case of talipes varus I did not break "the bone" over again, but, aided by one of Kolbe's shoes, I succeeded in enabling the child to walk with ease and comfort.

Yours,
W. R. D. BLACKWOOD.

Sept. 12, 1874.

TO THE EDITOR OF THE PHILADELPHIA MEDICAL TIMES:

IN the *Medical Times* of August 29, 1874, Dr. James D. McGaughey gives the details of a case of infantile convulsions successfully treated by chloral hydrate after numerous other remedies had been tried without avail. On the 26th day of July, 1874, I made use of chloral in a case of convulsions occurring in a child five years of age, but it failed to give any relief. I had never heard of its being used in such cases, but thought it would prove very beneficial. I gave it a fair trial, and it failed, where chloroform acted finely.

Yours truly,
T. J. TURPIN, M.D.

FORKLAND, ALA., Sept. 9, 1874.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY, FROM SEPTEMBER 15 TO SEPTEMBER 21, 1874, INCLUSIVE.

WRIGHT, J. P., SURGEON.—Assigned to duty as Chief Medical Officer, District of New Mexico. S. O. 96, District of New Mexico, September 7, 1874.

HUNTINGTON, D. L., ASSISTANT-SURGEON.—Relieved from duty in Department of the Columbia, and, in addition to his duty as member of Medical Examining Board, to report in person to the Commanding General, Department of California, for assignment to duty. S. O. 203, A. G. O., September 6, 1874.

BROOKE, JNO., ASSISTANT-SURGEON.—Assigned to duty at Fort Cape Disappointment, W. T. S. O. 124, Department of the Columbia, September 4, 1874.

KINSMAN, J. H., ASSISTANT-SURGEON.—Leave of absence extended to November 1, 1874. S. O. 205, A. G. O., September 18, 1874.

LAUDERDALE, J. V., ASSISTANT-SURGEON.—Assigned to duty at Fort Wingate, New Mexico. S. O. 143, Department of the Missouri, September 10, 1874.

EWEN, C., ASSISTANT-SURGEON.—Granted leave of absence for twenty days from October 1, 1874, on condition that he furnish, at his own expense, a suitable substitute during his absence. S. O. 135, Department of the Gulf, September 9, 1874.
